---

[1] Cost (cents-per-hour worked) measured in the Employment Cost Index consists of wages, salaries and employer cost of employee benefits.

[2] Consist of private industry workers (excluding farm and household workers) and State and local government (excluding Federal Government) workers.

[3] Consists of legislative, judicial, administrative, and regulatory activities.

[4] Includes, for example, library, social, and health services.

---

[1] The indexes are calculated differently from those for the occupation and industry groups. For a detailed description of the index calculation, see the *Monthly Labor Review* Technical Note, "Estimation procedures for the Employment Cost Index," May 1982.

25. Specified compensation and wage adjustments from contract settlements, and effective wage adjustments, private industry collective bargaining situations covering 1,000 workers or more (in percent)

Measure	Annual average		Quarterly average							
			1984				1985			
	1984	1985	I	II	III	IV	I	II^{p}	III^{p}	IV^{p}
Specified adjustments:										
Total compensation [1] adjustments, [2] settlements covering 5,000 workers or more:										
First year of contract	3.6	2.6	5.1	3.5	2.7	3.7	3.6	3.5	2.0	2.0
Annual rate over life of contract	2.8	2.7	4.7	3.2	3.1	2.0	2.7	3.4	3.0	1.4
Wage adjustments, settlements covering 1,000 workers or more:										
First year of contract	2.4	2.3	2.8	2.6	2.1	2.3	3.3	2.5	2.0	2.1
Annual rate over life of contract	2.4	2.7	3.3	2.7	2.6	1.5	3.2	2.8	3.1	1.9
Effective adjustments:										
Total effective wage adjustment [3]	3.7	3.3	.9	.9	1.2	.7	.8	.8	1.2	.5
From settlements reached in period	.8	.7	.1	.1	.2	.3	.1	.2	.2	.2
Deferred from settlements reached in earlier periods	2.0	1.8	.4	.7	.7	.2	.6	.5	.6	.2
From cost-of-living-adjustments clauses	.9	.8	.3	.2	.3	.2	.1	.1	.4	.1

---

[1] Compensation includes wages, salaries, and employers' cost of employee benefits when contract is negotiated.

[2] Adjustments are the net result of increases, decreases and no changes in compensation or wages.

[3] Because of rounding total may not equal sum of parts.

[p] = preliminary.

26. Average specified compensation and wage adjustments, major collective bargaining settlements in private industry situations covering 1,000 workers or more during 4-quarter periods (in percent)

Measure	Average for four quarters ending--							
	1984				1985			
	I	II	III	IV	I	II^{p}	III^{p}	IV^{p}
Specified total compensation adjustments, settlements covering 5,000 workers or more, all industries:								
First year of contract	4.8	4.7	4.2	3.6	3.4	3.5	3.1	(1)
Annual rate over life of contract	3.6	3.5	3.2	2.8	2.6	2.7	2.7	2.8
Specified wage adjustments, settlements covering 1,000 workers or more:								
All industries

[1] Data do not meet publication standards.

[p] = preliminary.

27. Average effective wage adjustments, private industry collective bargaining situations covering 1,000 workers or more during 4-quarter periods (in percent)

Effective wage adjustment	Average for four quarters ending–						
	1984			1985			
	II	III	IV	I	II^p	III^p	IV^p
For all workers:[1]							
Total	4.3	4.2	3.7	3.6	3.5	3.5	3.3
From settlements reached in period	1.0	1.0	.8	.7	.9	.9	.7
Deferred from settlements reached in earlier period	2.2	2.1	2.0	2.2	1.9	1.8	1.8
From cost-of-living-adjustments clauses	1.1	1.2	.9	.7	.7	.8	.8
For workers receiving changes:							
Total	5.3	5.0	4.4	4.5	4.2	4.3	4.1
From settlements reached in period	3.6	3.7	3.0	2.9	2.9	2.8	3.4
Deferred from settlements reached in earlier period	4.8	4.2	4.0	4.2	3.9	3.7	3.7
From cost-of-living-adjustments clauses	4.0	3.2	2.7	2.3	2.3	2.8	2.2

[1] Because of rounding total may not equal sum of parts.

p = preliminary.

28. Specified compensation and wage adjustments from contract settlements, and effective wage adjustments, State and local government collective bargaining situations covering 1,000 workers or more (in percent)

Measure	Annual average		Second 6 months 1985^p
	1984	1985	
Specified adjustments:			
Total compensation [1] adjustments, [2] settlements covering 5,000 workers or more:			
First year of contract	5.2	4.2	3.8
Annual rate over life of contract	5.4	5.2	5.3
Wage adjustments, settlements covering 1,000 workers or more:			
First year of contract	4.8	4.6	4.4
Annual rate over life of contract	5.1	5.4	5.6
Effective adjustments:			
Total effective wage adjustment [3]	5.0	5.8	4.1
From settlements reached in period	1.9	4.1	3.2
Deferred from settlements reached in earlier periods	3.1	1.8	.9
From cost-of-living-adjustment clauses	(4)	(4)	(4)

[1] Compensation includes wages, salaries, and employers' cost of employee benefits when contract is negotiated.

[2] Adjustments are the net result of increases, decreases and no changes in compensation or wages.

[3] Because of rounding total may not equal sum of parts.

[4] Less than 0.05 percent.

p = preliminary.

29. Work stoppages involving 1,000 workers or more

Measure	Annual totals		1985											1986	
	1984	1985	Feb.	Mar.	Apr.	May	June	July	Aug.	Sept.^{p}	Oct.^{p}	Nov.^{p}	Dec.^{p}	Jan.^{p}	Feb.^{p}
Number of stoppages:															
Beginning in period	62	–	4	4	3	2	2	9	6	11	4	2	2	–	–
In effect during period	68	–	13	12	8	6	8	13	18	20	18	11	8	–	–
Workers involved:															
Beginning in period (in thousands)	376.0	–	29.3	15.2	6.2	6.9	15.7	52.3	15.3	69.5	74.6	25.0	8.2	–	–
In effect during period (in thousands)	391.0	–	43.9	48.2	14.1	14.8	28.5	60.2	66.8	93.9	117.3	64.6	38.1	–	–
Days idle:															
Number (in thousands)	8,499.0	–	250.3	698.5	229.5	203.3	454.3	500.2	869.7	931.4	1,433.0	651.2	665.4	–	–
Percent of estimated working time[1]	.04	–	.01	.03	.01	.01	.02	.02	.03	.04	.06	.03	.03	–	–

[1] Agricultural and government employees are included in the total employed and total working time: private household, forestry, and fishery employees are excluded. An explanation of the measurement of idleness as a percentage of the total time worked is found in 'Total Economy' Measure of Strike Idleness,' *Monthly Labor Review*, October 1968, pp. 54-58.

[1] Area is generally the Standard Metropolitan Statistical Area (SMSA), exclusive of farms. L.A.-Long Beach, Anaheim, Calif. is a combination of two SMSA's, and N.Y., N.Y.-Northeastern N.J. and Chicago, Ill.-Northwestern Ind. are the more extensive Standard Consolidated Areas. Area definitions are those established by the Office of Management and Budget in 1973, except for Denver-Boulder, Colo. which does not include Douglas County. Definitions do not include revisions made since 1973.

[2] Foods, fuels, and several other items priced every month in all areas; most other goods and services priced as indicated:.

M - Every month.
1 - January, March, May, July, September, and November.
2 - February, April, June, August, October, and December.

[3] Regions are defined as the four Census regions.

The population size classes are aggregations of areas which have urban population as defined:

A-1 - More than 4,000,000.
A-2 - 1,250,000 to 4,000,000.
B - 385,000 to 1,250,000
C - 75,000 to 385,000.
D - Less than 75,000.

Population size class A is the aggregation of population size classes A-1 and A-2.

– Data not available.

NOTE: Local area CPI indexes are byproducts of the national CPI program. Because each local index is a small subset of the national index, it has a smaller sample size and is, therefore, subject to substantially more sampling and other measurement error than the national index. As a result, local area indexes show greater volatility than the national index, although their long-term trends are quite similar. Therefore, the Bureau of Labor Statistics strongly urges users to consider adopting the national average CPI for use in escalator clauses.

Italy	-	-	6.0	5.8	5.8	5.9	5.9	6.2	6.3
Sweden	-	-	-	-	-	-	-	-	-

[1] Quarterly rates are for the first month of the quarter.

[2] Major changes in the Italian labor force survey, introduced in 1977, resulted in a large increase in persons enumerated as unemployed. However, many persons reported that they had not actively sought work in the past 30 days, and they have been provisionally excluded for comparability with U.S. concepts. Inclusion of such persons would more than double the Italian unemployment rate shown.

- Data not available.

NOTE: Quarterly figures for France, Germany, and Great Britain are calculated by applying annual adjustment factors to current published data and therefore should be viewed as less precise indicators of unemployment under U.S. concepts than the annual figures.

46. Annual data: Employment status of the civilian working-age population, ten countries

---

[1] Total cases include fatalities.

[2] The incidence rates represent the number of injuries and illnesses or lost workdays per 100 full-time workers and were calculated as:
(N/EH) X 200,000, where:
N = number of injuries and illnesses or lost workdays.
EH = total hours worked by all employees during calendar year.
200,000 = base for 100 full-time equivalent workers (working 40 hours per week, 50 weeks per year.)

[3] Excludes farms with fewer than 11 employees since 1976.

– Data not available.

SALES PUBLICATIONS

BLS Bulletins

Consumer Expenditure Survey: Interview Survey, 1982-83. Bulletin 2246, 193 pp., $7.50 (GPO Stock No. 029-001-02888-1). Presents income and expenditure data for 1982-83 in detail from the Interview component of the ongoing Consumer Expenditure Survey.

Occupational Employment in Manufacturing Industries. Bulletin 2248, 133 pp., $5.00 (GPO Stock No. 029-001-02862-8). Presents the findings of the 1983 survey of occupational employment in 20 manufacturing industries.

Worklife Estimates: Effects of Race and Education. Bulletin 2254, 33 pp., $5 (GPO Stock No. 029-001-02889-0). Incorporates methodological improvements in estimates of working life for men and women introduced in 1982; contains a discussion of changes in expectancy since 1977, and updated and expanded tables for 1980, including the effects of race and educational attainment on expectancy.

Area Wage Surveys

These bulletins cover office, professional, technical, maintenance, custodial, and material movement jobs in major metropolitan areas. The annual series of 70 is available by subscription for $103 per year. Individual area bulletins are also available.

Dallas—Fort Worth, Texas, Metropolitan Area, December 1985. Bulletin 3030-66, 42 pp., $1.75 (GPO Stock No. 829-001-00066-7).

Dayton, Ohio, Metropolitan Area, December 1985. Bulletin 3030-59, 31 pp., $1.25 (GPO Stock No. 829-001-00057-4).

Denver—Boulder, Colorado, Metropolitan Area, December 1985. Bulletin 3030-67, 40 pp., $1.75 (GPO Stock No. 829-001-00067-5).

Jacksonville, Florida, Metropolitan Area, December 1985. Bulletin 3030-60, 42 pp., $1.75 (GPO Stock No. 829-001-00060-8).

Portland, Maine, Metropolitan Area, December 1985. Bulletin 3030-63, 29 pp., $1.25 (GPO Stock No. 829-001-00063-2).

Sacramento, California, Metropolitan Area, December 1985. Bulletin 3030-69, 26 pp., $1.25 (GPO Stock No. 829-001-00069-1).

San Diego, California, Metropolitan Area, December 1985. Bulletin 3030-68, 29 pp., $1.25 (GPO Stock No. 829-001-00068-3).

Periodicals

CPI Detailed Report. Each issue provides a comprehensive report on price movements for the month, plus statistical tables, charts, and technical notes. $4 ($25 per year). The November issue features an article on reconciling two measures of consumer price change in the third quarter of 1985.

Current Wage Developments. Each issue includes selected wage and benefit changes, work stoppages, and statistics on compensation changes. $2 ($21 per year). December issue features Employment Cost Index for September 1985.

Employment and Earnings. Each issue covers employment and unemployment developments in the month plus regular statistical tables on national, State, and area employment, hours, and earnings. $4.50 ($31 per year). January 1986 issue features an article on the revision of seasonally adjusted labor force series. February issue features articles on changes in the estimation procedure in the Current Population Survey beginning in January 1986 and the introduction of a new measure of part-time employment.

Occupational Outlook Quarterly. Each issue helps people planning careers, guidance counselors, manpower development specialists and others keep informed of changing occupational opportunities. $3 ($11 per year). Winter issue features articles on MBA's, roustabouts in the oilfields, farm operators and managers, recreational therapists, computer training, and recording engineers.

Producer Price Indexes. Each issue includes a comprehensive report on price movements for the month, plus regular tables and technical notes. $4.25 ($29 per year). December issue features price highlights in 1985.

U.S. Department of State Indexes of Living Costs Abroad, Quarters Allowances, and Hardship Differentials. January 1986. Tabulations computed quarterly by the Department of State for use in establishing allowances to compensate American civilian government employees for costs and hardships related to assignments abroad. The information is also used by many business firms and private organizations to assist in establishing private compensation systems. $2.75 ($10 per year).

To Order:

Sales Publications: Order bulletins by title, bulletin number, and GPO stock number from the Superintendent of Documents, U.S. Government Printing Office, Washington, D.C. 20402, or from the Bureau of Labor Statistics, Publications Sales Center, P.O. Box 2145, Chicago, IL 60690. Subscriptions, including microfiche subscriptions, are available only from the Superintendent of Documents. All checks—including those that go to the Chicago Regional Office—should be made payable to the Superintendent of Documents.

Other Publications: Request from the Bureau of Labor Statistics, U.S. Department of Labor, Room 2421, 441 G Street, N.W., Washington, D.C. 20212, or from the Bureau of Labor Statistics, Chicago Regional Office, P.O. Box 2145, Chicago, IL 60690.

BLS Data Diskettes now available

BLS data users now can store and manipulate the Bureau's data series on their personal, IBM-compatible microcomputers

The following data diskettes are formatted for use with LOTUS 1-2-3:

Monthly

Employment, hours, and earnings from the establishment survey—national monthly and annual average data for 256 industrial series for the current year-to-date and the 3 prior years. Single diskette, $35. Annual subscription of 12 monthly diskettes, $288.

Labor force, employment, and unemployment from the Current Population Survey—monthly and annual average information on the employment and unemployment experience of the Nation's population classified by age, sex, and race for 282 series for the current year-to-date and the 3 prior years. Single diskette, $35. Annual subscription of 12 monthly diskettes, $288.

Producer Price Indexes—selected commodity groupings by stage of processing for the most recent 13 months. Single diskette, $35. Annual subscription of 12 monthly diskettes, $288.

Quarterly

Employment Cost Index–quarterly measures of change in total compensation (wages, salaries, and employer costs for employee benefits) and in wages and salaries only; 180 series beginning in 1980–81 and 120 series from 1975 to the most recent quarter. Single diskette, $35. Annual subscription of 4 quarterly diskettes, $104.

National productivity indexes—63 quarterly labor productivity and cost measures for business, nonfarm business, nonfinancial corporations, and manufacturing from 1947 to the current quarter. Also, 24 annual multifactor productivity measures (output per unit of combined labor and capital inputs) for private business, private nonfarm business, and manufacturing from 1948 to the current year. Single diskette, $35. Annual subscription of 8 quarterly diskettes, $196.

U.S. export and import price indexes—quarterly export and import price indexes for 450 Standard Industrial Trade Classification categories for the most recent 8 quarters. Single diskette, $35. Annual subscription of 4 quarterly diskettes, $104.

Annual

Economic projections to 1995—average annual output, total employment, hours, and wage and salary employment for 1984 and projected 1985–95 for 150 industries. Single diskette, $35.

Foreign labor statistics–129 annual indexes of manufacturing productivity and labor costs for the United States and 11 foreign countries from 1950 to 1984; and levels of the labor force, unemployment, and related measures for the United States and 9 countries from 1959 to 1984. Single diskette, $35. Annual subscription of 4 quarterly diskettes, $104.

Industry productivity data—annual indexes showing change over time in the relationship between the output of an industry and the employee hours expended on the output for over 130 industries: most start in 1958 and go to the most recent year. Also, annual Federal Government productivity indexes showing the change over time in the relationship between the output of the combined organizations within a function and the employee years expended on that output from 1967 to 1984. Single diskette, $35.

Occupational injury and illness data—annual number of work-related injuries and illnesses or lost workdays per 100 full-time employees from 1981 to 1984. Single diskette, $35.

MONTHLY LABOR REVIEW

MAY 1986
VOLUME 109, NUMBER 5

Henry Lowenstern, Editor-in-Chief
Robert W. Fisher, Executive Editor

NEWARK PUBLIC LIBRARY

MAY 2 8 1986

U. S. GOVT. PUBS.
DEPOSITORY 378

Patrick J. McMahon 3 **An international comparison of labor force participation, 1977–84**
Comparisons of labor force participation in six countries, including the U.S., show vastly different patterns, both overall and for different demographic groups

H. Brand, C. Huffstutler 13 **Trends of labor productivity in metal stamping industries**
Overall growth in the annual rate of output per employee hour was sluggish in 1963–83, but performance was stronger in 1972–83 for the producers of automotive parts

E. Jay Howenstine 21 **Foreign housing voucher systems: evolution and strategies**
European governments have historically used housing allowance concepts, with strategies which include a model for workers based on labor mobility

CONFERENCE PAPERS

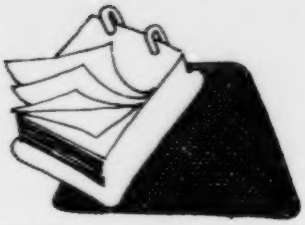
Labor Month In Review



KLEIN AWARD. The Lawrence R. Klein Award trustees selected two authors of the best articles published in the *Monthly Labor Review* in 1985 as winners of the 17th annual Klein Award. The award was presented at the Bureau of Labor Statistics awards ceremony on April 28. Award for the best *Review* article by a BLS author went to Neal H. Rosenthal, chief of the Division of Occupational Outlook, for "The shrinking middle class: myth or reality?" in the March issue. Winner of the best article written by an author outside of the BLS was Helen Ginsburg, professor of economics at Brooklyn College, for "Flexible and partial retirement for Norwegian and Swedish workers," in the October issue.

The Rosenthal article presents an analysis of statistical data that might better inform the debate stirred by recent articles suggesting a decline in the middle class—defined as middle income earners—claiming that most of the new jobs are at the top and bottom of the earnings structure. Rosenthal focused primarily on how changes in occupational structure and wage levels affect the distribution of earnings of individuals in 1973 and 1982. He arrayed 416 occupations by earnings and arranged them into three earnings groups—bottom, middle, and top; summed the number of workers and occupations in each earnings group; and calculated a percent distribution of employment.

He explains, "If the proportion of middle income earners are declining, the proportion of total employment in the middle would show a decline between 1973 and 1982, and the bottom and top, an increase." The analysis shows an increase for the top group, a modest decrease for the middle and a decrease for the bottom. Rosenthal concludes, "Changes in occupational structure alone from 1973 to 1982 do not support the notion of bipolarization."

The combined effect of changes in relative wages and in occupational structure of workers over the 1973-82 period show total employment increasing for the top and middle income groups and decreasing for the bottom. This, states Rosenthal, "Indicates a shift of workers from the low to the middle and high earnings levels...."

According to Rosenthal, the middle class is not declining, although, he says, "Some trends in the industrial and occupational structure of employment could cause a degree of earnings bipolarization. However, a multitude of factors have an effect on the occupational structure of our economy an on the earnings of workers in specific occupations. Although not all factors can be quantified, an analysis of available data indicates that the combined effect of all factors apparently has not caused bipolarization over the 1973-82 period. Also, given BLS projections of employment by occupations, bipolarization is not likely to occur between 1982 and 1995."

The Ginsburg article focuses largely on the Swedish retirement plan because of its greater popularity, more widespread use, and because it offers an unusual degree of flexibility in both age and extent of retirement, compared with the Norwegian plan. Ginsburg discussed the plans of the two countries—noting that a major difference is that Sweden's plan encourages partial retirement *prior* to normal retirement age, while the Norwegian plan encourages it *after* the normal retirement age.

Under the Swedish partial pension plan, a person age 60 to 64 can reduce his or her work hours, receive full pay for the time worked, and also receive a pension to replace 50 percent of the lost earnings, up to a limit. Work time must be reduced by at least 5 hours a week, and after reduction, must average at least 17 hours weekly. Also, to be eligible, a person must have had pensionable earnings for at least 10 years after age 45 (unemployment and sickness benefits are pensionable income in Sweden), and must have been gainfully employed for at least 5 of the last 12 months.

Although not designed to be a weapon against unemployment, Ginsburg notes, partial pensions act as a form of worksharing, preventing employee dismissals in some cases and working against (but not eliminating) the tendency to take early retirement.

Ginsburg concludes, "Developments in Norway and Sweden, which have a more elderly population than the United States, could provide the starting point for a discussion of a comprehensive older-worker policy in the United States."

About the award. Trustees of the Klein Award Fund are Lawrence R. Klein; Charles D. Stewart, president; Ben Burdetsky, secretary-treasurer; Peter Henle; Harold Goldstein; Howard Rosen; and Henry Lowenstern. The award was established in 1968 in honor of Lawrence R. Klein, editor-in-chief of the *Monthly Labor Review* for 22 years until his retirement in 1968. Instead of accepting a retirement gift, Klein donated it and matched the amount collected to initiate the fund. Since then, he has contributed regularly to the fund as have others. The purpose of the award is to encourage *Review* articles that (1) exhibit originality of ideas or method of analysis, (2 adhere to the principles of scientific inquiry, and (3) are well written. Each winning article carries a cash prize of $200.

Tax-deductible contributions to the fund may be sent to Ben Burdetsky, Secretary Treasurer, Lawrence R. Klein Fund, c/o School of Government and Business Administration, The George Washington University, Washington, DC 20052. □

An international comparison of labor force participation, 1977–84

International comparisons of labor force participation in six countries, including the United States, show vastly different patterns, both overall and for demographic groups

Patrick J. McMahon

Over the past decade there have been substantial changes in the structure and performance of labor markets in most countries. These changes stem from changes in various economic factors such as the oil price crises in 1974 and 1978 and the subsequent slowdown in economic growth and emergence of international recession. However, labor force responses since 1975 to these changes have varied considerably between countries and the outcomes may usefully be compared and contrasted. In this article, six countries with similar approaches to labor force measurement are compared.[1] The largest is the United States, followed by Japan and West Germany. The smallest markets considered are, in order of size, Canada, Australia, and Sweden.

The aggregate participation rates in each country are shown in table 1. The range is large. Sweden had the highest labor force participation rate, followed by Canada, the United States, Japan, Australia, and West Germany.[2]

The overall changes in labor force participation since 1975 are also shown in table 1. In Australia the labor force participation rate fell 1.7 percentage points from 61.6 percent in 1975. West Germany and Japan experienced little change in the aggregate participation rate. By contrast, labor markets in the other countries were characterized by large growth in participation rates, particularly in Canada and the United States. In Sweden, which had the highest proportion of the working age population in the labor force of any country considered, the participation rate rose by slightly less.

The magnitude and nature of these different changes in the aggregate labor force participation rate can be seen more clearly by examining the change in the labor force participation rate (shown in column 3) decomposed into the change in the employment-population ratio (shown in column 4) and, completing the identity, the change in the unemployment-population ratio.[3]

In all countries but the United States, the employment-population ratio either increased by less than the participation rate or fell between 1975 and 1984. Australia and West Germany also stand apart from the remaining countries, having experienced both a large decline in employment growth relative to population growth and hefty increases in unemployment. The fall in participation in Australia decomposes into a large fall in the employment-population ratio accompanied by a smaller offsetting increase in unemployment. In West Germany, contrary to the Australian experience, the effect of a fall in the employment-population ratio was completely offset by an increase in unemployment. In Japan, almost all of the small increase in the participation rate was attributable to a small increase in the employment-population ratio, while, in Canada, most of the increase in participation rate decomposes into a dominant increase in unemployment. In Sweden, both employment and unemployment grew roughly by the same magnitude, at least according to the official "unadjusted data" for the popula-

Patrick J. McMahon is an economist, Australian Bureau of Labour Market Research. He wrote this article while visiting the Bureau of Labor Statistics, U.S. Department of Labor.

tion aged 16 to 74. BLS estimates, shown as the "unadjusted data" for the population aged 16 and over, suggest that in Sweden the participation rate altered predominantly from an increase in unemployment with very little change in the employment-population ratio.

Of all the countries examined, the Australian and U.S. experiences appear to be unique at either end of the spectrum. Only Australia experienced a large decline in the participation rate together with a very large increase in the unemployment-population ratio, and only the United States experienced a large increase in the participation rate together with a decline in the unemployment-population ratio.

Changes in composition

Observed changes in the labor force may reflect shifts in the age and sex structure of the population, changes in labor force behavior within demographic groups, or both. The role of composition effects vis-á-vis behavioral influences is examined in this section.

The effect of demographic changes can be measured by computing the aggregate participation rate for 1984, maintaining the 1975 participation rates for each individual demographic group. The difference between the 1975 and the 1984 rate calculated by assuming no participation change in the demographic components indicates that change in the participation rate was due solely to demographic shifts. Between 1975 and 1984, demographic shifts would have marginally altered the aggregate participation rates of the United States, Canada, and Sweden. (See table 2.) More substantial shifts occurred in Australia (down 1.1 percentage points), Japan (down 1.1 percentage points), and West Germany (up 0.8 percentage points).

After adjusting for demographic factors, West Germany appears to have had similar experiences to Australia. Thus Australia and West Germany were the only countries to have experienced behaviorally induced declines in aggregate labor force participation *and* large increases in unemployment.

Participation rates by sex

The participation rates of men and women are shown for each country in table 3. Male participation rates varied little between most countries but the rate for West Germany was particularly low. In 1984, Japan had the highest rate (78.9 percent), followed by Canada, the United States, Sweden, Australia, and West Germany which had the lowest (71.9 percent).

Between 1975 and 1984, male labor force participation fell in all countries. Australia experienced the largest change, from 80.5 to 75.7 percent, and the United States the smallest, from 77.9 to 76.4 percent. Most of these changes were because of shifts in behavior rather than demographic factors as the following tabulations of the percentage point change due to the effect of demographic change show:

Australia	−0.3	Sweden	−0.2 (unadjusted) or 0.1 (BLS adjusted)
Canada	0.6	United States	0.5
Japan	−0.6	West Germany	0.7

Female participation rates varied considerably between countries and the Australian and West German rates were low, compared with Sweden, the United States, Canada, and Japan.

Female participation rates rose in all countries but the magnitude of the increases varied widely. The rates rose markedly in Canada, Sweden, and the United States. Small increases were recorded in Japan, West Germany, and Australia.

Estimates of the change in participation, net of the effects of demographic shifts, result in large gains in Canada, Sweden, and the United States, moderate gains in Japan and Australia, and a very small increase in West Germany.

The conclusion is that changes in labor force participation rates for both men and women in all countries mainly reflect changes in behavior. It would appear, however, that demographic influences are important in contrasting changing patterns of female labor force participation in Australia with

Table 1. Labor force participation rates and the relative shares of changes in employment and unemployment to changes in labor force participation, six countries, 1975 and 1984[1]

Country	Labor force participation rate		Employment-population ratio		Percentage point change in the:		
	1975	1984	1975	1984	Labor force participation rate	Employment-population ratio	Unemployment-population ratio
Australia	61.6	59.9	58.8	54.8	−1.7	−4.0	2.3
Canada	61.1	64.8	56.9	57.4	3.7	0.5	3.2
Japan	63.0	63.5	61.9	61.8	0.5	−0.1	0.6
Sweden:							
Unadjusted	69.6	71.9	68.5	69.6	2.3	1.1	1.2
BLS adjusted[2]	65.9	67.0	64.8	64.9	1.1	0.1	1.0
United States	61.2	64.4	56.1	59.5	3.2	3.4	−0.2
West Germany[3]	55.5	55.6	53.6	51.6	0.1	−2.0	2.1

[1] Refers to annual average data in Canada, Sweden, the United States, and Japan (except for 1984, where an 11-month average was used). The data for Australia refer to the August survey and were chosen because it is the only month for which a historically consistent time series exists. The data used for West Germany are from the microcensus and are collected each April/May. The microcensus data were chosen because they are the only labor force data collected in West Germany which conform to International Labor Organization concepts and definitions.

[2] The published Swedish data are shown as "unadjusted" and refer to the population aged 16 to 74. BLS calculations of the labor force participation rate and employment-population ratios for the population aged 16 and over are shown as "BLS adjusted."

[3] The latest data available are for 1983 and the data refer to that year.

those that occurred in West Germany.

Further insights can be gained by considering separately the change in the male and female participation rates relative to the change in employment. Between 1975 and 1984, most of the decline in male labor force participation occurred on the employment side with offsetting increases in unemployment. Large declines in employment were significant in Australia and West Germany, and to a lesser extent, Canada. Modest rises in employment occurred in Japan and Sweden. The United States contrasts with all other countries, but particularly Australia and West Germany. The United States had the smallest decline in the male employment-population ratio and was the only country to achieve an improvement in the male unemployment-population ratio.

Similarly, much of the increase in female participation occurred on the employment side with relatively small increases in unemployment. This holds for all countries except Australia and West Germany. In these countries, unemployment increases accounted for much of the rise in participation rates. Again the United States contrasts starkly. The United States recorded the largest increase in the female employment-population ratio and at the same time was the only country able to achieve an improvement in the unemployment-population ratio.

Demographic groups

Comparisons of labor force participation of various demographic groups in the six countries highlight the reasons why Australia and West Germany have performed so poorly relative to the other countries, and the United States in particular. The groups compared are teenagers and young adults, prime working age persons (aged 25 to 54), and older persons (aged 55 and over).[4]

Teenagers and young adults. The youth labor market is conventionally split into teenage (that is, aged 15 to 19 or 16 to 19) and young adult (aged 20 to 24) groups for analysis, because each component typically exhibits different labor force behavior. These differences are usually reflected in differentiated policy interest in the two groups.

The participation rates of teenagers in each country are shown in table 4. The variation is remarkable. In 1984, for example, the participation rate for female teenagers ranged from 55.7 percent in Australia to only 18.4 percent in Japan.

Between 1975 and 1984, large differences between countries are evident in both the direction and magnitude of change in teenage labor force participation rates. Large declines were recorded in teenage participation rates of Sweden and West Germany. The participation rates of Swedish teenagers fell from 59.0 to 43.8 percent for males and from 56.2 to 47.0 percent for females.[5] West German teenage male participation rates fell from 57.2 to 46.1 percent for males and from 50.7 to 38.6 percent for females. In contrast, small declines in teenage participation rates were recorded in Australia and Japan for both males and females.[6] In the United States and in Canada, male teenagers recorded small declines while small increases were recorded for female teenagers.

Table 2. Estimates of contributions of demographic and behavioral changes to labor force participation rate changes, 1975 and 1984[1]

Country	Participation rate			Change in participation rate due to:	
	1975	1984	1984 using 1975 weight	Demographic shift	Behavioral shift
Australia	61.6	59.9	60.5	−1.1	−0.6
Canada	61.1	64.8	61.0	−0.1	3.7
Japan	63.0	63.5	61.9	−1.1	1.6
Sweden:					
Unadjusted	69.6	71.9	69.4	−0.2	2.5
BLS adjusted	65.9	67.0	66.0	0.1	1.0
United States	61.2	64.4	61.3	0.1	3.1
West Germany[2]	55.5	55.6	56.3	0.8	−0.7

[1] Refers to annual average data in Canada, Sweden, the United States, and Japan (except for 1984, where an 11-month average was used). The data for Australia refer to the August survey and were chosen because it is the only month for which a historically consistent time series exists. The data used for West Germany are from the microcensus and are collected each April/May. The microcensus data were chosen because they are the only labor force data collected in West Germany which conform to International Labor Organization concepts and definitions.

[2] The latest data available are for 1983 and the data refer to that year.

As seen above, changes in age composition could explain the changes observed. In Sweden, roughly half of the fall in the male teen participation rate (7.6 of 16.3 percentage points) was because of shifts in the age composition. Among female teenagers, demographic effects should have raised the participation rate 0.2 percentage points but actually it fell 6.9 percentage points. In Canada, demographic effects should have increased the male teen participation rate 1.3 percentage points but it fell 0.6 percentage points. Demographic changes should have increased the female teen participation rate 1.4 percentage points, but the actual increase was 3.3 percentage points. Similarly, in the United States demographic effects should have raised participation rates of male teens by 0.6 percentage points and female teens by 0.4 percentage points but, the actual changes were −3.1 and +2.7 percentage points. In other words, the evidence suggests that demographic influences are swamped by behavioral changes, at least in Sweden, Canada, and the United States, the only countries for which the data is available at a low level of aggregation.

The usual explanation of declining teenage participation rates is that increasing proportions of young people are staying in school. This argument is consistent with teenage participation rate trends in Sweden, West Germany, and Japan. In Australia, Canada, and the United States, however, substantial increases in teenage labor force participation have occurred among teenagers still in school.

The nature of the change in teenage participation rates can be better appreciated by considering the relative contribution of employment and unemployment changes. In Australia and West Germany, many were unable to find work because the growth in employment substantially lagged the

Table 3. Labor force participation rates and the relative shares of employment and unemployment to changes in the labor force participation of men and women six countries, 1975 and 1984

Country and Sex	Labor force participation rate			Employment-population ratio		Percentage point change in the:		
	1975	1984	1984 using 1975 weights	1975	1984	Labor force participation rate	Employment-population ratio	Unemployment-population ratio
Men:

Women:								
Australia	43.0	44.6	41.3	40.3	40.9	1.6	0.6	1.0
Canada	44.4	53.5	43.7	40.8	47.3	9.1	6.5	2.6
Japan	45.7	49.0	44.1	45.0	47.6	3.3	2.6	0.7
Sweden:								
Unadjusted	59.2	67.5	59.4	58.0	65.3	8.3	7.3	1.0
BLS adjusted[3]	55.2	61.5	54.5	(2)	(2)	6.3	(2)	(2)
United States	46.3	53.6	46.0	42.0	49.5	7.3	7.5	- 0.2
West Germany[4]	38.8	41.0	39.3	37.4	37.5	2.2	0.1	2.1

[1] Refers to annual average data in Canada, Sweden, the United States, and Japan (except for 1984, where an 11-month average was used). The data for Australia refer to the August survey and were chosen because it is the only month for which a historically consistent time series exists. The data used for West Germany are from the microcensus and are collected each April/May. The microcensus data were chosen because they are the only labor force data collected in West Germany which conform to International Labor Organization concepts and definitions.

[2] Unfortunately, separate estimates of employment of the sexes aged 75 and over were not available to calculate the relevant employment-population ratios.

[3] The published Swedish data are shown as "unadjusted" and refer to the population aged 16 to 74. BLS calculations of the labor force participation rate and employment population ratios for the population aged 16 and over are shown as "BLS adjusted."

[4] The latest data available are for 1983 and the data refer to that year.

growth in the population. In the United States, the situation would appear to be entirely different, unemployment changed little and even improved slightly for female teenagers.[7] In Canada, employment and unemployment changes substantially offset each other for men, but for women most of the increased participation was reflected in increased unemployment. In all other countries, substantial declines in the teenage employment-population ratio occurred with little or no increase in unemployment.

There has been less of a difference between the countries in the participation rate trends of young adults than for teenagers. Australia, along with Canada and the United States, had the highest male young adult participation rates in 1984. (See table 4.) Sweden and West Germany had rates that lay midway on the range, and Japan had a relatively low rate, 70.9 percent.

Male young adult participation rates have changed very little over time in all countries except Japan.[8] Participation rates fell there from 76.5 to 70.9 percent, which may reflect the strong move towards further education.

Some differences were apparent in the relative importance of changes in the employment component vis á vis the unemployment component to changes in young adult male participation rates. Almost all of the large decline in Japan reflected declines in employment with little or no unemployment effect. In all other countries, except the United States, declines in employment were largely offset by increases in unemployment. These were substantial in Australia and Canada, and to a lesser extent in West Germany. Only in the United States was there an increase in the employment-population ratio of young adult men and a reduction in the unemployment-population ratio.

The participation rates of young women were lower than those for men. In 1984, the rate for women ranged from 80.4 to 68.9 percent, and was highest in Sweden, followed by Canada, Australia, West Germany, the United States, and Japan.

In recent years, the labor force participation rates of young women have increased markedly in all countries except West Germany, where the rise was much smaller. The reasons for this upsurge were mainly the expansion of the service sector (which employs large numbers of women), increased opportunities in part-time labor markets, and declining fertility.[9] The very high labor force participation rate of young women in Sweden has also reflected changes in taxation arrangements for married women, the introduction of parenthood insurance in the 1970's, and government-financed child care centers.[10]

The relative contributions of employment and unemployment changes to these increases varied considerably between the countries. Only in the United States, which achieved the largest increase in the female young adult employment-population ratio of any country, was there a reduction in the unemployment-population ratio. Japan also achieved strong employment growth with a small increase in unemployment. West Germany was the only country to experience an actual decline in the employment-population ratio, with a substantial increase in unemployment. Canada had the lowest increase in the employment-population ratio, but the largest increase in unemployment, while Australia and Sweden experienced more moderate increases in both.

Prime working age persons. Prime working age men (aged 25 to 54) have the highest participation rates of any population subgroup. (See table 4.) Unlike other age groups, there has been little change in the labor force participation of prime working age men in any of the countries considered. In 1984, Japan had the highest rate followed by Sweden, West Germany, the United States, Australia, and Canada. The close similarity across all countries is not surprising, however, given the high degree of labor market attachment of men in the prime working age range.

While Australia had the second highest prime working age male participation rate in 1975 (96 percent), it had the second lowest rate in 1984 (93.6 percent). This decline has been larger than in any other country and, although small in magnitude, is highly significant given the degree of labor force commitment by prime working age men. Moderate declines were experienced in Canada and West Germany, and slight declines occurred in Sweden, the United States, and Japan.

The participation of prime working age men are hardly affected by shifts in the age composition of this group. These shifts would have marginally increased participation rates in Australia (0.4 percentage points), Canada (0.1 percentage points), Sweden (0.2 percentage points), and the United States (0.3 percentage points), and marginally decreased participation in West Germany (0.1 percentage points) and Japan (0.1 percentage points). Behavioral, rather than demographic, influences were important.

These declines in prime working age participation rates are generally attributed to the variety of governmental programs and subsidies (for example, sickness and disabilities payments and retraining programs) available to persons not in the labor force or wishing to leave it. It has also been argued that the increasing participation of married women has relieved prime working age men of the burden of being the sole family breadwinner. In theory, these changes give these men opportunities to reduce their participation, although in practice there are no studies to suggest that these factors have any significant effect.

While the changes in all countries were small, some quite different patterns have emerged in the relative contributions of changes in employment and unemployment. Participation has declined since 1975 in Australia, Canada, and West Germany because their historically large declines in employment were not wholly offset by increases in unemployment. However, the declines were double those of most countries. Japan, the United States, and Sweden have recorded slight declines in participation among prime working age men since 1975, but these changes were predominantly the result of a small decline in employment, relative to the population, with a smaller increase in unemployment.

Unlike the male participation patterns, enormous changes have occurred since 1975 in the labor force participation of prime working age women. Again major differences are apparent between Australia and West Germany and the other countries. In 1984, female labor force participation was still lowest in Australia (55 percent) and West Germany (57.1 percent) and highest in Sweden (88.1 percent). The American, Canadian, and Japanese rates were much higher than Australia and West Germany, but still were well below those for Sweden.

Between 1975 and 1984, the participation rate of prime working age women rose 12 to 16 percentage points in Canada, Sweden, the United States, and Japan. Much less spectacular rises were recorded in Australia (6.7 percent) and West Germany (5.9 percent).

Changes in the age composition of prime working age women again had very little influence on their participation rate. Changes in age composition would have raised the participation rate in Australia by 1.6 percentage points, Japan by 1.0 percentage points, Sweden by 0.4 percentage points, Canada by 0.3 percentage points, and West Germany by 0.2 percentage points and would have lowered the rate in the United States by 0.1 percentage points. Once again, we believe that behavioral, not demographic, changes were important.

Several reasons appear important in explaining these patterns of change in behavior. The expansion of employment in the service sector and the expansion of part-time employment opportunities. Both of these areas of employment tend to be dominated by women in most countries (particularly Australia, Canada, Sweden, and the United States). However, in Japan, female employment in the service sector has been much lower than in other countries, and there are comparatively few women in part-time employment in West Germany.[11]

These developments suggest that an increase in employment opportunities is a major reason for the upsurge in the labor force participation of prime working age women and this is borne out by an examination of the sources of labor force participation changes. In Canada, Japan, Sweden, and the United States (all of which have had the largest increases since 1975), the increases resulted from large increases in employment and small changes in unemployment. Even in Australia, the employment increases were still dominant. Only in West Germany were increases in unemployment larger than employment growth.

Declining fertility rates are also frequently cited as important in the marked upsurge in prime working age female labor force participation. In the last two decades, fertility rates have fallen in most Western countries except Sweden (which already had a very low rate in the 1960's) and Japan (where fertility has actually risen slightly over the last two decades). Other reasons often cited are the radical improvements in "household technology" and the development of commercial substitutes for household products—dryclean-

Table 4. Labor force participation rates and the relative shares of employment and unemployment to changes in the labor force participation of selected age groups, six countries, 1975–1984[1]

Age, sex, and country	Labor force participation rate		Employment-population rate		Percentage point change in the:		
	1975	1984	1975	1984	Labor force participation rate	Employment-population ratio	Unemployment-population ratio
Teenagers[2]

[1] Refers to annual average data in Canada, Sweden, the United States, and Japan (except for 1984, where an 11-month average was used). The data for Australia refer to the August survey and were chosen because it is the only month for which a historically consistent time series exists. The data used for West Germany are from the microcensus and are collected each April/May. The microcensus data were chosen because they are the only labor force data collected in West Germany which conform to International Labor Organization concepts and definitions.

[2] Teenagers refer to 15- to 19-year-olds in Australia, Canada, Japan, and West Germany, and to 16- to 19-year-olds in Sweden and the United States.

[3] The latest data available were for 1983 and the data refer to that year.

ing, fast-foods, restaurants—which have released female labor for the market place. Finally, improved education among women may have shifted their preferences in favor of work outside the home.

The comparatively small increase in prime working age female participation in West Germany probably reflects the historical importance of foreign workers at times of employment expansion and this may have restricted the opportunities for women to successfully enter the labor force. The guest worker has not been significant since the early 1970's but neither has there been a significant employment expansion. While female participation rates have generally been lower in Europe, the higher rates in North America and Scandinavia are now beginning to be replicated in other European countries and the differences currently observed are probably differences in timing and in the overall pace of job growth.

Older persons. People aged 55 and over are defined here as "older persons." The group is split into those aged 55 to 64 and those aged 65 and over, because the participation rates of the latter group are substantially lower than those of the former.

The participation rate of men aged 55 to 64 in 1984 was lower in Australia and West Germany than in most other countries. The rate was relatively high in Japan, Sweden, Canada, and the United States. (See table 4.)

The changes in the participation rate of these men since 1975 have been quite different between Australia and other countries. A particularly large drop was observed in Australia. A large decline was also recorded in Canada. Modest decreases were observed in Sweden and the United States, and only a marginal decline was observed in Japan. While a modest decline was also observed in West Germany, it occurred from an already low base.

Shifts in the age composition of this group should have raised participation rates in West Germany (6.3 percentage points) and lowered participation rates in the United States (0.2 percentage points), Australia (0.3 percentage points), and Sweden (0.5 percentage points). Similar computations could not be made for Canada or Japan. This suggests that age composition effects were insignificant explanations of the overall declines. The age composition effect calculation also shows that the behavioral shifts in West Germany are much greater than indicated by a comparison of participation rates over time.

Declines in the participation rates of older men in Australia and in most countries reflect large declines in employment. In Australia and Canada, the participation drop was because of a decrease in the employment-population ratio with little change in unemployment. The declining participation of older men reflects trends towards earlier retirement ages and the expansion of pension schemes. The reasons for a high participation rate and very small declines in participation in Japan are also related to cultural factors and the pension system, which is not generous.[12]

The trends in the labor force participation rates of older women aged 55 to 64 have been rather different than those of older men. The participation rate of women aged 55 to 64 in 1984 ranged from a low 19.8 percent in Australia to 59.6 percent in Sweden.

Since 1975, there have been small declines in the participation rates of older women in Australia. In the same period, very small increases were recorded in the United States, Canada, Japan, and West Germany. A large increase was recorded in Sweden.

Shifts in the age composition of this group would have raised participation rates by an insignificant amount in the United States (0.3 percentage points) and lowered it by an insignificant amount in Australia (1.5 percentage points). However, the increase in the participation rate of German women aged 55 to 64 is illusory because demographic shifts should have increased the participation rate by 2.5 percentage points.

Much more variation in participation rates and their employment and unemployment components was evident for older women aged 55 to 64 than for men. For women of this age group, participation declined only in Australia, reflecting a large drop in employment which was not offset by a small rise in unemployment. In West Germany, a slight increase in participation reflected small increases in employment and unemployment. In Sweden, the United States, and Japan, increased participation was almost entirely brought about by rises in employment.

The main feature of these comparisons is that substantial declines in the labor force participation rates of older men have occurred in all countries, yet those trends have not been replicated for older women. In Australia the declines that occurred for women were much smaller than those for men, and in West Germany, Canada, Sweden, Japan, and the United States, an increase in participation was actually observed.

In 1984, the between-country ranking of labor force participation rates for men aged 65 and over was similar. The rate was markedly higher in Japan than in the United States, Canada, Sweden, Australia, and West Germany.

The labor force participation rates of women aged 65 and over in 1984 ranged widely between countries, from 16.3 percent in Japan to 2.5 percent in Australia. The Australian rate was also considerably lower than that of the United States. Only in West Germany did the rate approach that in Australia. The Australian rates have, however, always been low relative to other countries. In the last decade the participation rate in Australia has gradually declined from around 4 percent to 2.5 percent. Declines in the labor force participation rates of women aged 65 and over in other countries have been marginal in the last 10 years.

Conclusions

A comparison of the change in labor force participation rates, decomposed into changes in the employment and unemployment-population ratios, shows a large disparity in job creation capability between the United States and many other advanced nations. The contrasts between the two extremes—the United States, on one hand, and Australia and Germany, on the other, are illustrative. Australian and West German participation rates, adjusted for change in the demographic composition of the labor force, fell between 1975 and 1984. Underlying these behaviorally induced declines in labor force participation were large declines in employment relative to population growth and hefty increases in the unemployment-population ratio. By contrast, the United States experienced a large behaviorally induced increase in the participation rate, accompanied by strong growth in the employment ratio and a small decline in the unemployment-population ratio.

Comparisons of labor force participation rates for demographic groups also confirm Australia's and Germany's poor performance relative to the rest, and to the United States in particular. In both, large withdrawals from the labor force, especially among older men, and small increases in female participation rates occurred. Modest falls in male participation rates and enormous increases in female rates occurred in the United States and to a lesser extent in the other countries. These changes suggest substantial increases in unemployment, both recorded and hidden, in Australia and Germany, and estimates suggest a jobless rate of almost double the official rate in Australia and one and a half times it in Germany.[13] □

[2] The published Swedish participation rate is even higher (71.9 percent in 1984). Part of the explanation of why the published Swedish rate is so high is that the labor force is expressed as a proportion of the population aged 16 to 74. In other countries no maximum age is used to restrict the numbers in the working age population. The BLS has estimated that the inclusion of the population aged 75 and over would reduce the participation in 1984 by around 5 percentage points. The BLS estimates are used here.

[3] These components of the labor force participation rate are conventionally referred to as ratios. Strictly speaking, however, they are rates as the ratios are expressed in percentage terms. For instance, the employment-population ratio is calculated as the ratio of the number employed to the number in the working age population multiplied by 100. The unemployment-population ratio is similarly calculated. It is also important to stress than an examination of labor force participation rate changes in terms of the relative contributions of the employment-population and unemployment-population ratios does not imply anything about the underlying casual factors which have led to participation changes. For instance, if participation rate changes were largely because of changes in the employment-population ratio, it does not necessarily mean that the change was demand-determined. Similarly, participation rate changes that were mainly caused by changes in the unemployment-population ratio are not necessarily supply-determined. Finally some comments on the use of the unemployment-population rather than a conventional unemployment rate are needed. The unemployment-population ratio is used for convenience because it completes the identity. If the reader feels more comfortable with an unemployment rate this can easily be calculated by dividing the unemployment-population ratio by the participation rate.

[4] In the United States and Sweden, the young age groups refer to men and women aged 16 to 24, and in Sweden, the older age groups refer to men and women aged 55 to 74.

[5] Measurement differences may complicate the interpretation of these figures. For instance, in Sweden, unlike in other countries, all full-time teenage students who are looking for work are automatically not counted as unemployed. However, this should make a minor contribution to the difference observed. The differences in the age definitions of teenagers also affects the figures. Teenagers are defined as persons aged 15 to 19 in Australia, Canada, Japan, and West Germany, and as 16 to 19 years of age in Sweden and the United States. Comparisons of specific cohorts within the teenage group are possible between Australia and Canada and Australia and the United States but when this is done it becomes apparent that the bulk of the difference in teenage labor force participation between countries is primarily due to differences in participation behavior rather than to differences in the age distribution or measurement of the teenage population.

[6] Between 1975 and 1981 male teenage partipation rates in Australia increased to 62.0 percent and female rates declined marginally to 57.0 percent.

[7] It should be noted, however, that a large teenage unemployment problem already existed in 1975 which was not evident in most of the other countries.

[8] It was not possible to analyze the effects of changing age composition among young adults because none of the countries published data for subcomponents.

[9] By the same argument, differences in the rate of change will also reflect differences in fertility and education, as well as labor force factors identified here.

APPENDIX: International differences in measuring the labor force

Scope, coverage, and method of labor force surveys

The approach to regular monthly labor force measurement in Australia, Canada, Japan, Sweden, and the United States is the "labor force" or "activity" approach in accordance with the standard International Labor Organization (ILO) guidelines for the definition and measurement of labor market concepts. In West Germany, an annual microcensus of the population is also taken, from which measures of the labor force are made according to the activity approach and this is used in the article.

Similar multistage sampling methods are used in Australia, Canada, Japan, and the United States. Households are selected according to geographical location, and persons within these households are interviewed. In contrast, samples of *persons* which represent the population are selected in Sweden and West Germany. There is no reason to expect that differences in sample selection methods will lead to any significant bias in the result obtained for each country.

Some bias could result from differences in sample rotation and from differences in data collection methods. Households remain in the Australian survey for 8 months and in the Canadian survey for 6 months. In Japan, households are surveyed for 2 consecutive months in 1 year, leave the survey, and rejoin it again for the same 2 consecutive months in the following year. The U.S. system is identical except that households are surveyed for the same 4 consecutive months in each of the 2 years. In the Swedish survey, persons are interviewed once every 3 months over a 2-year period, whereas, in West Germany, a new sample is selected for each annual microcensus. However, the nature and direction of any rotation group bias that may exist in surveys has not been determined.

Differences in definitions and major concepts

The working age population is defined as those persons aged 15 and over in Australia, Canada, Japan, and West Germany. It is defined as those aged 16 and over in the United States and as those aged 16 to 74 in Sweden. In addition, the working age population refers to the civilian noninstitutionalized population in Canada and the United States; to the civilian population in Australia and West Germany; and to the total resident population in Japan and Sweden.

The importance of differences between countries in defining the working age populations to include or exclude noncivilians and institutionalized persons is difficult to determine in the absence of relevant data for all countries. Differences in the minimum age of the working age population are likely to be more important, particularly with respect to comparisons of teenage labor markets. Similarly, the maximum age of 74 in Sweden will have some effect on both older worker and aggregate labor force participation rate comparisons between Sweden and the other countries, but adjustments are made in the tables to include persons 75 years of age and older.

The major concept underlying the employment definition is that of work for payment during the survey week. In Australia, Japan, Sweden, and West Germany, employment refers to at least 1 hour for payment. In Canada and the United States, it is any work at all for payment. The classification of persons who worked without pay in a family business as employed persons, also differs between countries. Unpaid family workers are counted as being employed if they work at least 15 hours in the survey week in Australia, Sweden, and the United States. This same group are counted as being employed if they only worked at least 1 hour in the survey week in Japan or in West Germany, and if they did any work at all during the survey week in Canada. The other dimension of the employment definition is that of persons who had a job but were not at work during the survey week. Here the differences between countries are minor. It is unlikely that any of these differences in the definitions of employment will have any more than a marginal effect on labor force comparisons between countries.

Differences in the various definitions of unemployment appear to be greater than those for either the working age population or employment. Persons who did not have a job in the survey week but had actively looked for work and were available for work are classified as unemployed. However, the available for work criterion is not used in West Germany. The main difference in unemployment definitions between countries is the time period specified as that in which active job search was carried out in order to be classified as unemployed. In Australia, Canada, and the United States this period is the *4 weeks* up to the end of the survey week. In Sweden it is *60 days* up to the end of the survey week. This will lead to higher estimates of unemployment in Sweden, than is the case for other countries. In contrast, in Japan and West Germany *no period is actually specified.* Constance Sorrentino has shown that, in Japan at least, this may well result in a tendency of job search activities to be counted only if they occurred in the survey week, thereby leading to consistently lower estimates of unemployment. On the other hand, Sorrentino has also shown that a large number of those counted as unemployed in Japan did not seek work during the month. This would be those people who have applied for employment over a month ago but who have not received a reply from their employer. This would lead to an overestimate of the unemployed. On balance, the Japanese unemployment rate is slightly understated. The position for West Germany, however, is unknown.

Two other dimensions of the unemployment definition are important. First, temporary unemployment which did not involve active job search, such as waiting to return to a job from a temporary absence (not including illness or vacation) or waiting to start a new job in the near future, is counted as unemployment in all countries except Japan, where such persons are classified as not in the labor force. Second, in all countries except Sweden, full-time students are classified as being employed if they had a job or as being unemployed if they were actively looking for work. In Sweden, full-time students are counted as being outside the labor force during school terms even if they are actively looking for work. These factors mean that estimates of unemployment in Japan and Sweden will be lower than in other countries.

In each country the labor force is defined as all those who were counted as employed or unemployed during the survey week. The residual of the working age populations are classified as inactive or not in the labor force.

Published and adjusted labor force data

Only those countries for which data were available and measured according to the standard ILO guidelines (that is, via the activity approach) were considered for selection in the international comparisons made in this article. Other countries were not considered because their regularly published labor force statistics are measured in a very different way and are not directly comparable with those derived from the activity approach. Hence, the approach adopted here has been to use the published labor force data from those countries for which comparable *activity* data were available.

An alternative approach to making international labor force comparisons would be to use data from various countries that have been *adjusted* to U.S. labor force concepts and definitions. Adjusted data exists for the broad aggregates and are published by the BLS. The ways in which the data are adjusted are outlined in Constance Sorrentino, *International Comparisons of Unemployment*, BLS Bulletin 1979, Washington, DC, 1978; and Constance Sorrentino, "International comparisons of labor force participation, 1960–81," *Monthly Labor Review*, February 1983, pp. 23–36. Adjustment of data to U.S. concepts and definitions has not been made for the detailed age groups examined here.

A note on communications

The *Monthly Labor Review* welcomes communications that supplement, challenge, or expand on research published in its pages. To be considered for publication, communications should be factual and analytical, not polemical in tone. Communications should be addressed to the Editor-in-Chief, *Monthly Labor Review*, Bureau of Labor Statistics, U.S. Department of Labor, Washington, D.C. 20212.

Trends of labor productivity in metal stamping industries

Overall growth in the annual rate of output per employee hour was sluggish from 1963 to 1983, but performance was stronger during 1972–83 for producers of automotive stampings, while it weakened in the nonautomotive stampings industry

HORST BRAND AND CLYDE HUFFSTUTLER

Labor productivity, or output per employee hour, in the metal stamping industry rose at an average annual rate of 1 percent over the two decades, 1963–83.[1] Output rose at about the same rate, while employee hours remained on balance unchanged over the period. Between 1963 and 1973, productivity advanced more rapidly (1.2 percent a year) than over the following decade (0.7 percent). The earlier annual improvement was associated with fairly strong output and employment gains, while the subsequent advance resulted from a declining trend in output being exceeded by a declining trend in employment. The longer term productivity performance in terms of average annual rates of change was much lower than for all manufacturing.

	Metal stampings	*All manufacturing*
1963–83	1.0	2.4
1963–73	1.2	2.6
1973–83	0.7	1.9

The productivity trend for the 20-year period examined here was marked by much volatility. In almost half of the 20 years, productivity declined, although by small magnitudes. These declines were almost invariably associated with larger drops in output than in employee hours—a pattern frequently encountered in durables manufacturing industries during business slumps. In only 7 years of the period did productivity rise because output gains topped employee hour increases. All these years occurred during an expansionary phase of the business cycle (table 1).

Year-to-year fluctuations in productivity ranged from a fall of 4.0 percent (in 1964) to a rise of 8.6 percent (in 1971), with the more typical movements running between plus or minus 3 percent. However, underlying these movements were often large swings in output and employee hours. For example, the productivity increase of 4 percent in 1976 was linked with output and employee hour rises of 22 and 17 percent. Both of these variables had plummeted by 19 and 16 percent the preceding year—with productivity receding by only 3 percent.

Component industries

Data for metal stampings industry establishments were treated as one industry until 1972. The industry was then reclassified into three separate industries, for two of which

---

Horst Brand and Clyde Huffstutler are economists in the Division of Industry Productivity and Technology Studies, Bureau of Labor Statistics. Norman D. Bennett aided in research for this report.

separate measures for productivity and related variables are published and discussed here—automotive and nonautomotive metal stampings.[2] The productivity trends for these two industries diverged considerably over the 1972-83 span, rising at an average annual rate of 1.8 percent for the former, and declining 0.7 percent a year for the latter. These movements reflect much stronger average annual growth for automotive metal stampings after 1977, and a much sharper decline for nonautomotive stampings.

	Automotive	*Nonautomotive*
1972–83	1.8	−0.7
1972–77	0.7	−0.4
1977–83	2.5	−2.2

The productivity improvement in the automotive metal stamping industry reflected a long-term decline in output of 1.5 percent annually, accompanied by a 3.2-percent-a-year drop in employee hours. The downward trend in nonautomotive metal stampings, on the other hand, resulted from moderately rising output (0.7 percent a year), and a somewhat higher employee hour rate (1.3 percent). The high productivity growth after 1977 for automotive metal stampings was associated with sharply declining output and even more pronounced decreases in employee hours. The productivity drop in nonautomotive metal stampings was also associated with falling output, but employee hours fell less.

Output and demand

The automotive metal stampings industry manufactures fenders, roofs, exhaust systems, brake shoes, trim, and other motor vehicle stamping components. These larger stampings are usually made in establishments operated by automobile companies. The industry also manufactures such products as brackets, valves, and other smaller items. These products are usually made by smaller, independent suppliers. Nonautomotive stampings consist of a vast array of job stampings often made in comparatively small batches; kitchen, household, and other utensils; pressed metal for such uses as storefronts, curtain walls, and refrigerators; and enclosures for electronic or electrical apparatus. Nonautomotive metal stampings are made mostly by smaller firms. (See below.)

Output of the combined metal stamping industries rose at an average annual rate of 0.9 percent over the 1963–83 span, but its rise during the first decade, 2.3 percent a year, was replaced by a drop during the second (−0.7 percent annually). This slowdown in the industries' output typified the output pattern of all durable manufactures over the period: for these, the annual rate of growth averaged 5 percent for 1963–73, but only 0.7 percent for 1973–83.

Demand for metal stampings stems mostly from other hard goods industries.[3] Thus, while the number of domestically made motor vehicles rose 1.8 percent a year during the 1963–73 period, it dropped 3.4 percent annually thereafter—these trends being closely matched, first, by a 4.1-percent-a-year rise, then by a 1.4-percent-a-year fall in the output of automotive metal stampings. (The larger output rates of automotive metal stampings stem from the demand for replacement stampings in addition to original equipment stampings.)

Output of automotive metal stampings was probably also slowed by imports of motor vehicles during the 1970's and early 1980's. As a proportion of new supplies of motor vehicles, imports rose from 13.6 percent in 1972 to 23.8 percent in 1981. Import penetration of parts of motor vehicles, which often embody metal stampings, rose from 7.7 to 9.1 percent. The import penetration of automotive metal stampings as such rose but slightly, barely exceeding 1 percent in 1981. However, imports classified as metal stampings are likely to have been dwarfed by imports of automotive products, of which metal stampings are an integral component.

Hard goods industries other than motor vehicles, and for which the Bureau of Labor Statistics has computed measures, likewise experienced slower growth (or declines) during the 1973–83 decade, as compared with 1963–73—a development that accounts for the parallel output trend pattern of nonautomotive metal stampings (a 2.3-percent-a-year rise followed by a 2.1-percent-a-year drop). Included in such hard goods industries are construction machinery, agricultural equipment, pumps and compressors, internal combustion engines, and refrigeration and heating equipment.[4] All these industries purchase job stampings, which accounted for nearly one-half of the total value of nonauto-

Table 1. Indexes of output per employee hour, output, and employee hours in metal stamping industries, 1963–83

[1977=100]

Year	Output per employee hour: All employees	Output per employee hour: Production workers	Output per employee hour: Nonproduction workers	Output	Employee hours: All employees	Employee hours: Production workers	Employee hours: Nonproduction workers

motive metal stampings shipped in 1982, according to the Census of Manufactures.

The output slowdown in metal stampings noted for the 1972–83 period occurred largely between 1977 and 1983 (average annual rates in percent):

	1972–83	*1972–77*	*1977–83*
All hard goods	1.7	1.7	−0.5
Automotive metal stampings	−1.5	0.2	−5.0
Number of domestic motor vehicles	−3.4	0.5	−8.8
Nonautomotive metal stampings	0.7	−0.4	−2.8

Employment and hours

In 1983, the metal stamping industries employed close to 194,000 persons. Levels of employment ran 13 percent higher than in 1963, but they had receded 18 percent from their peak in 1978. Much of the rise in total 1963–83 employment, and little of the drop that occurred in recent years, took place among nonproduction workers. Production worker employment ran 10 percent higher in 1983 than in 1963, but in 1983 it still stood 20 percent below 1978.

On balance, however, the long-term trend in employment and hours in the metal stamping industries was flat. Employee hours rose at an average annual rate of 1.3 percent over the first decade of the review period, then dropped by a like magnitude over the second. Employment increased slightly faster in 1963–73 (1.9 percent a year) than employee hours, and declined a bit slower in 1973–83 (1.1 percent annually). Employment and hours in hard goods manufacturing generally paralleled these trends.[5]

The long-term trend in production jobs did not increase significantly over the 20-year span, while nonproduction employment rose at a 1-percent-a-year rate. Whereas a gain in production jobs during the 1963–73 decade was reversed thereafter, the increase in nonproduction workers merely leveled off.

The following illustrates the evolution of employee hours during the 1970's in both metal stampings industries (average annual rates of change, in percent):

	Automotive	*Nonautomotive*
1972–83	−3.0	3.3
1972–77	−0.5	0.0
1977–83	−7.3	−0.6

Production worker hours declined somewhat more than nonproduction worker hours in automotive metal stampings. But in nonautomotive metal stampings their decline contrasted with a considerable and sustained increase in nonproduction worker hours. By the end of the period, the proportion of nonproduction workers in nonautomotive metal stampings had expanded to 29 percent of total employment from 20 percent in 1972—a pattern similar to all durable manufacturing, in which the proportion of nonproduction workers had grown to 34 percent from 27 percent in 1972. In automotive metal stampings, nonproduction workers accounted for 15 percent of all employment, not much different from 11 years earlier. The employment of women progressed in relative terms—from 10 to 15 percent of the total in automotive metal stampings, and from 26 to 29 percent in nonautomotive stampings. (In all of durable manufacturing, women's employment grew from 21 to 26 percent over the 1972–83 period.)

Attesting the highly cyclical nature of the demand for automotive metal stampings, and evidently also management policies that linked output (or demand) fluctuations with employment practice, labor turnover rates in the industry ran well above the manufacturing average from 1972 to 1981[6]—as well as above the average for nonautomotive stampings. High labor turnover tends to dilute the levels of skill and experience of the work force. Such dilution (or loss) was made up to an extent by high overtime schedules in automotive metal stampings that averaged 35 percent above manufacturing for the 11 years examined here. In nonautomotive stampings, overtime ran 7 percent below.[7]

	Automotive	*Nonautomotive*
	(Manufacturing = 100)	
Accessions	119	108
Separations	124	111
Layoffs	264	118

The occupational composition of the two metal stamping industries is more heavily weighted toward production workers than manufacturing as a whole. In 1982, professional, technical, and managerial personnel accounted for 4 percent of total employment in industry group SIC 346

Table 3. Indexes of output per employee hour, output, and employee hours in the nonautomotive metal stamping industry, 1972–83

[1977 = 100]

Year	Output per employee hour			Output	Employee hours

(metal forgings and stampings).[8] The corresponding percentage for manufacturing as a whole was 10 percent. Craft and related workers represented 27 percent of the group's employment, compared with 19 percent for all manufacturing. The differences stemmed in part from the two industries' high proportion of tool and die makers (6 percent versus 1 percent). Forty-four percent of the industry group's workers were operatives (versus 41 percent in manufacturing)—with machine tool and punch press operators making up the bulk of the employees in this category (35 percent versus 6 percent for manufacturing).

The level of, as well as the trend in, relative hourly wages was not quite so favorable in nonautomotive stampings as in automotive stampings. In 1983, these amounted to 87 percent of the durables manufacturing average, down from 94 percent in 1972. In automotive stampings, by contrast, the wage relative stood at 130 in 1983, not much different from its 1972 level.

Technological change

Both metal stamping industries discussed here convert steel mill products of varying thicknesses into a vast range of components used in capital goods and consumer durables.[9] Examples have been noted. The basic apparatus used in both industries consists of production presses. Such presses are considered to be metalforming machine tools, although unlike metalcutting machine tools they cannot reproduce themselves. Production presses have been defined as being essentially power-operated clamps that close one or more dies at a proper speed and pressure.[10] The die or dies with which a press is equipped shear, bend, or otherwise "distort" the sheet or strip fed to it, forming the desired shape. The metal is generally worked cold.

Presses vary widely in size and in the amount of power—usually expressed in terms of tonnage of pressure— they bring to bear. The die may be single purpose, as when a workpiece is simply cut out or shaped, or it may be a "progressive" or a transfer die, imparting complex shapes to the workpiece. Progressive dies, which may consist of as many as nine work stations, subject the workpiece to several sequential strokes or punches. In such operations, the steel is usually fed automatically from coils through the several work stations as a continuous ribbon of material up to the last station of the die, where the part is sheared off. Manual feeding of strip steel remains widely prevalent.[11]

According to the most recent *American Machinist* inventory of metalworking machinery, 30 percent of the metalcutting and 20 percent of the metalforming machine tools installed in the industry sector to which the two metal stamping industries belong were less than 10 years old in 1983—a somewhat lower proportion of such relatively up-to-date equipment than had been reported in the *American Machinist*'s 1973 inventory.[12] About one-third of the two industries' stock of machine tools was between 10 and 20 years old in 1983, also a lower proportion than a decade earlier. Close to two-fifths of metalcutting and nearly one-half of metalforming machine tools were 20 or more years old in 1983, considerably higher than in 1973.[13] There has thus occurred a degree of aging in the two industries' basic equipment. However, industry sources believe that such aging may have been partially offset by rebuilding and retrofitting of the older machine tools with updated components. The importance of rebuilding and retrofitting may be inferred from the rise in machine tool manufacturers' shipments of parts of metalforming machine tools, from 19 to 24 percent of total shipments between 1967 and 1972, and to around 29 percent in recent years.[14] Also confirming the importance of retrofitting is the fact that about one-third of all metalcutting machine tools and one-fourth of all metalforming machine tools in the two metal stamping industries feature numerical controls. The production capabilities of machine tools so equipped are generally higher than those without numerical controls. (See below.)

The advent of numerical controls, first applied in metalforming in the punching of flat metal in the 1950's, stimulated new press designs. It probably also contributed to a shift of some metalworking from metalcutting to metalforming machine tools, inasmuch as it helped in improving the precision of the latter. Thus, metal stampings made for automotive castings and forgings, which formerly were finished by metalcutting, came to be completed in one operation by means of metalforming. Filter system components, brake and wheel components, gasoline engine mufflers, oil filter caps, engine mounts and brackets, some kinds of gear, as well as metal cabinets for computers and other electronic devices have come to be made by stamping presses.[15] The shift evidently improved productivity significantly, for per-unit costs were reportedly reduced by as much as one-half.[16]

Numerical controls, in addition to enhancing the precision of production presses, have also made higher production speeds possible. For turret punch machines (a type of power press), setup time has been virtually eliminated, as numerical controls can automatically change punch configurations. Unit costs of short production runs have been drastically reduced as manual setups have been replaced by taped programs fed to the mechanism that controls the punch magazine.[17] Numerical controls have also facilitated rapid alternation of punching movements between the x and y or other coordinates of a workpiece. The introduction of computer numerical controls in the early 1970's, where installed, has done away with the coordinate calculation required by numerical controls.[18]

There exist tens of thousands of smaller punch presses operated manually or by foot, and equipped with an auxiliary electrical motor. Technological advances have evidently been minor here, particularly where little power is needed and production runs are short, as, for example, in crimping or embossing. Mechanical feeding devices, however, do raise the speeds of hand- or foot-operated punch presses somewhat (such presses average 15 to 20 stampings per minute).[19]

Where the use of coil stock is feasible, automated feeding of the press has been widely introduced. With continued improvement in the physical stability and accuracy of presses, as many as 1,800 strokes per minute are attained in some jobs. Automatic ejection of parts, as well as automatic chopping and removal of scrap, becomes necessary at such speeds.[20]

Partly because of the shift of some metal fabrication from metalcutting to metalforming machine tools, partly because of the needs of such industries as computers, robotics, and instrumentation, and also because of international competition, the quality control requirements of the metal stamping industries became increasingly stringent during the review period. Hence, presses had to be designed to accommodate closer tolerances. For example, some 50-ton punch presses have had to operate within 5/1000 of an inch of accuracy, without sacrificing speed, hence, productivity.[21] Quality control devices, such as coordinate measuring instruments, have come to be linked directly to computers, which correct developing inaccuracies by way of feedback systems. Such installations have tended not only to economize on the labor inputs of quality control personnel, they have also tended to reduce rejects, and have made product improvements possible—for example, the removal of burrs on small metal parts.[22]

Notwithstanding the advances sketched here, and the competitive pressures to which both metal stamping industries are subject, both retain an expensive investment in older, at times outdated equipment (as the *American Machinist* inventory data cited also indicate). Thus, the generally lower capabilities of automotive metal stamping presses in the United States than in Japan are linked largely to the enormous inventories here of older dies which must be bolted into the press, and which are transported by cranes or forklift trucks. The Japanese, who built much of their metal stamping plant in the 1970's, clamp dies hydraulically, and move them to the press by means of tracked cars. Dies are removed from the press by being pushed from their trolleys into one of these cars, while a new die is loaded from the opposite side. American press dies cannot be retrofitted to accommodate this labor-saving setup. This is but one reason for the difficulty of adopting—or adapting—updated metal stamping technologies here in the near term.[23]

Capital investment

In terms of constant dollars,[24] automotive metal stamping establishments raised their capital expeditures at an average annual rate of about 9 percent, more than triple the rate for nonautomotive stamping establishments. Trends in the real value of capital investment in machinery and equipment also differed considerably between the two industries:

	Total	*Machinery and equipment*	*Structures and buildings*
Automotive metal stamping	9.2	11.8	−4.0
Nonautomotive metal stamping	2.6	4.7	−3.3
All manufacturing ...	4.5	–	–

A breakdown of capital expenditure data for all manufacturing is available only for 1972–81. Constant-dollar expenditures for machinery and equipment over that period rose by 7 percent a year, and a comparison with the rates for the two metal stamping industries suggests that the captial intensity of automotive metal stamping establishments increased at an above-average rate, while the reverse was true of nonautomotive metal stamping firms. As regards structures and buildings, while the rates for the two metal stamping industries declined, the rate for all manufacturing, at least for the 1972–81 period, rose 0.7 percent a year. The relative increase indicated in the capital intensity of automotive metal stamping shops is documented by the rise in their fixed assets per employee, from 134 to 153 of the manufacturing average (=100) over the 1972–82 span. In nonautomotive metal stamping firms, assets per worker declined slightly, from 68 to 66.

The long-term rates shown obscure the exceedingly large year-to-year fluctuations in the constant-dollar capital spending of both metal stamping industries. For example, capital spending by automotive metal stamping firms ranged from a rise of 69 percent (in 1977) to a drop of 48 percent in 1982. Gyrations in outlays for structures and buildings were even more pronounced. Comparable movements for all of manufacturing were much more moderate. It should be noted that nearly all of the decline in the two industries' spending rates for structures and buildings stems from cutbacks after 1978.

Structure of the metal stamping industries

The number of establishments in the two metal stamping industries together rose 25 percent between 1972 and 1982. All of the increase occurred among smaller firms with up to 49 employees, while a decline took place among firms with 100 workers or more. In automotive metal stampings, establishments with up to 49 employees accounted for 65 percent of the total in 1982, as against 46 percent in 1972; for nonautomotive shops, the comparable proportions read 82 percent versus 80 percent. However, the percentage of total employment in the smaller firms, while also higher in 1982 than a decade earlier, remained modest. It rose from 5 to 9 percent in automotive metal stampings, and from 27 to 34 percent in nonautomotive stampings.

Larger metal stamping establishments continued to account for a predominant share of employment in automotive stamping shops, and for close to one-half of it in the nonautomotive stamping industry. In the former, establishments with 100 workers or more represented 82 percent of the work force in 1982, in the latter 47 percent. Automotive stamping firms have, for the most part, been large employers, but nonautomotive stamping firms have been typically of modest size, with firms employing 500 workers or more accounting for but 12 percent of this industry's workers.

Automotive metal stamping averaged 135 employees per establishment in 1982, nonautomotive stamping shops, 37. The great differences in both employment size distribution as well as in average number of workers per establishment reflect in part the difference between fixed assets per worker, hence, the extent of business opportunities for persons knowledgeable in the trade. The figure was $23,773 for nonautomotive metal stampings, and $55,265 for automotive metal stampings in 1982 (for all manufacturing the figure read $36,146). Investment per worker in structures also was much lower in the former industry (around $5,400) than in the latter (about $10,800). (Here, the manufacturing average was $8,700.)

Outlook

Industry analysts generally foresee advances in stamping press technology which would raise operating time owing to such factors as improved ease of maintenance, and greater precision without loss of press speed. Robotic transfer and assembly too is likely to be introduced more widely. In turn, output per unit of labor input would be expected to rise. Among anticipated improvements, as well as improvements already on stream but not as yet broadly diffused are devices (such as die cushions) that slow the downward speed of the press. Downward speed accelerates after the punch has penetrated the upper portion of a given workpiece and resistance to the punch's force weakens. Unless the speed is inhibited, the press destabilizes, and this can lead to severe maintenance problems. Also, overload protection, which is designed into the clutch or hydraulic system controlling the press stroke, will likely be adopted by more metal stamping shops.[25]

Wider diffusion of solid state press controls is also expected. Such controls, which have no moving parts, usually eliminate the maintenance chores and problems associated with electromechanical controls. Diagnostic and self-check circuits are more easily incorporated in such controls, and at lower cost than in their electromechanical counterparts.[26]

Continuous-operating presses, equipped with progressive (or transfer) dies, and fed by automatic coil feed systems, are also seen to be more widely adopted. Such presses, with their high production capabilities, require but a single operator who monitors them. They completely fabricate a part with each stroke; that is, they permit the elimination of all secondary operations and multiple handling.[27] The reduction of die changing time from hours to a few minutes is also likely to become more widely prevalent. As noted, however, this requires the scrapping of existing presses, and large investments in technically more advanced ones, featuring quick die changing mechanisms. In addition, new die transportation systems would have to be installed.[28] The obsolescence of older presses and their dies, together with the force of international cost competition, may in time compel these investments.[29]

Precision requirements for metal stampings (as for other types of metalworking products) are expected to become more exacting in the years ahead, and small-batch production more frequent.[30] These developments spell increasing reliance of metal stamping establishments upon automated and computerized metalforming systems, as well as on die technologies that minimize setup changes. Electronic controls and digital readouts in the shearing, bending, and punching of blanks are also likely to be adopted by more shops. The pace of diffusion depends in some measure upon prospects of production cost savings, which, to be sure, in the two metal stamping industries tend to be clouded by demand cyclicality.

Marrying metal stamping to assembly processes for the thousands of fabrications the two industries produce (or will produce) remains a test of the innovativeness of the designers and builders of presses and their accessories.[31] The trend toward eliminating manual assembly, and of integrating the metalforming with the assembly process seems likely to become more pronounced.[32] This tends to do away with transfer operations. Thus, when two or more parts of a given workpiece are to be joined to make up a given fabrication, this can often already be done without loss of press stroke speed.[33]

Nevertheless, robotics as transfer devices are bound to continue to replace human labor in metal stamping—both automotive and nonautomotive. Where the size and complexity of some workpieces necessitate multistation press production lines, that is, where progressive dies are not feasible, transfer of the workpiece from one press to the next is increasingly likely to be done by robots.[34] Of course, short-run stamping operations will remain routine in many metal stamping operations, and these, so industry observers hold, will not soon become susceptible to robotics. Currently, 4,000 to 5,000 stampings of the same configuration are required to yield a reasonable payoff on any investment in robotizing feeding or tailing the press.[35] Where longer runs justify the introduction of robots, they are believed likely also to make a broader program of punch press automation economical.[36]

For the 1984–95 period, BLS has projected a rise of between 5 and 15 percent in the wage and salary employment of the industry group to which the two metal stamping industries belong. The occupational mix of the industry group is expected to shift somewhat toward more highly skilled workers. The proportion of operatives, such as punch press and assembly workers, has been projected to decline from 44 to 42 percent of the industry group's total employment, while that of craft and related workers rises from 27 to 29 percent. The projections presuppose that the technological advances anticipated in metalforming will not be significantly labor-displacing, or obviate the need for skilled personnel in the years ahead. ☐

FOOTNOTES

[1] The metal stamping industries discussed in this article include automotive metal stampings, designated by the Office of Management and Budget as SIC 3465 in the *Standard Industrial Classification Manual, 1972*; and metal stampings, not elsewhere classified (nonautomotive metal stampings), as SIC 3469. In addition to SIC 3465 and SIC 3469, the measures presented with this article also include crowns and closures (SIC 3466). Automotive stampings consist of such products as hubs, trim, and other parts of motor vehicles. Nonautomotive stampings include job stampings, household appliance housings and parts, and other porcelain enameled products; and cooking and other kitchen utensils. Crowns and closures include bottle caps made of stamped metal, and jar crowns, similarly made.

Average annual rates shown in the text and tables are based on the linear least square trend of the logarithms of the index numbers. The indexes for productivity and related variables will be updated annually, and published in the annual BLS bulletin, *Productivity Measures for Selected Industries*.

[2] Prior to 1972, establishments manufacturing all categories of metal stampings were designated as SIC 3461 by the Office of Management and Budget. Beginning in 1972, metal stamping products were regrouped in accordance with the classifications described in footnote 1. Crowns and closures, for which no separate measure has been published here, account for about 3 percent of the employment of the three industries together.

[3] See *The Detailed Input-Output Structure of the U.S. Economy, 1977* (U.S. Department of Commerce, Bureau of Economic Analysis, 1984). See also the tables pertaining to SIC 346. The pertinent industry chapter of the *1982 Census of Manufactures*, table 6a-1, also yields relevant information.

[4] Major industrial consumers of metal stampings where average annual rates in output declined between 1963–73 and 1973–83 include:

	1963–73	*1973–83*
Internal-combustion engines	6.2*	−0.7
Farm and garden machinery	3.2	−3.6
Construction machinery	4.1	−4.6
Machine tools	−1.6	−4.2
Pumps and compressors	3.7	1.1
Refrigeration and heating equipment	12.3*	−0.2
Transformers	7.5	−0.7
Motors and generators	1.7	−0.9
Major household appliances	4.0	0.7
Radio and TV receiving sets	3.3	1.8
Motor vehicles and equipment	4.6	−5.1

*1967–73.

[5] Trends in employment and hours in durable goods manufacturing (average annual rates in percent):

	Employment	*Employee hours*
1963–83	0.6	0.5
1963–73	2.1	2.2
1973–83	−0.9	−1.2

APPENDIX: Measurement techniques and limitations

Indexes of output per employee hour measure changes in the relation between the output of an industry and employee hours expended on that output. An index of output per employee hour is derived by dividing an index of output by an index of industry employee hours.

The preferred output index for manufacturing industries would be obtained from data on quantities of the various goods produced by the industry, each weighted (multiplied) by the employee hours required to produce one unit of each good in some specified base period. Thus, those goods that require more labor time to produce are given more importance in the index.

In the absence of adequate physical quantity data, the output indexes for the industries discussed here were developed using a deflated value technique. The value of shipments of the various product classes was adjusted for price
changes by appropriate Producer Price Indexes and Indu
Sector Price Indexes to derive real output measures. Th
in turn, were combined with employee hour weight

Foreign housing voucher systems: evolution and strategies

European governments have historically used housing allowance concepts with various strategies depending on the given definition of "most needy;" models include those with priority given to large families, the elderly, and the handicapped, and a model based on labor mobility

E. JAY HOWENSTINE

The "housing voucher" or "housing allowance" concept is emerging as the principal tool in U.S. housing subsidy policy. In Europe, governments have effectively operated national housing allowance systems for several decades with a wide variety of strategies. This report examines foreign experience.[1]

Two fundamental judgments underlie all housing allowance[2] systems: (1) there are large numbers of families that cannot obtain minimum standard housing by paying a reasonable portion of their income, and (2) the most needy households should be given first priority in the payment of housing subsidies. However, there have been notable differences among housing allowance systems in their approach to the most needy households. There have been different definitions of "most needy," and the principle of priority for the most needy has often been blended with other important economic and social purposes.

The strategic role of the housing allowance concept as it has developed in other countries can be best understood by delineating eight models of the concept: large family hardship model; elderly hardship model; rent harmonization model; excessive shelter-to-income model; tandem-new construction model; social stability model; labor mobility model; and family crisis model. (See exhibit 1.)

E. Jay Howenstine, an independent consultant, formerly was International Research Coordinator, Office of Policy Development and Research, U.S. Department of Housing and Urban Development. The views expressed are those of the author and do not necessarily reflect those of the Department.

Large family hardship model

The pre-World War II European perception was that wages of the working classes were more or less fixed over time. Other things being equal, therefore, an additional child in the family—and families tended to be big—led to a worsening of life in two major ways: a smaller portion of family income was available for the consumption of each individual; and each person had less physical space within the household.

In other industrialized nations, social concern for the welfare of children in large working class families found political expression in two ways rather different from the American experience, that is, in the establishment of family allowance systems (sometimes called children's allowances) and in social housing programs. Family allowance systems, spearheaded by the International Labour Office created under the League of Nations in 1919, were adopted in most of the highly industrialized countries providing financial assistance for each additional child in the family to avoid a lowering of standards of living.[3] And social housing (more or less the European equivalent of U.S. public housing) programs were promoted to help eliminate slums.

Because slums could only be avoided or eliminated by constructing more housing, it was logical that financial assistance should be in the form of producer subsidies to the builder, that is, mainly public and nonprofit agencies acting on behalf of the poor. The new social housing was then normally allotted on the basis of a point system to the most

Exhibit 1. Multiple uses of housing allowance strategies by foreign governments

Model	Countries and approximate date of adoption
1. Large family hardship	Sweden, 1930's France, 1948 Finland, 1962 Switzerland, Basle Canton, 1963 City of Zurich, 1963 Denmark, 1964
2. Elderly hardship	France, 1948 Sweden, 1950's Denmark, 1959 Switzerland, Basle Canton, 1963 Belgium, 1950's Australia, 1969 Finland, 1970 Canadian provincial systems, 1970's
3. Rent harmonization	France, 1948 Federal Republic of Germany, 1955 Denmark, 1967 Netherlands, 1967 Ireland, 1967 Austria, 1970's Norway, 1973
4. Excessive shelter-to-income ratio	Austria Federal Republic of Germar Finland Netherlands
5. Tandem-new construction	Norway, 1967 Sweden, 1960's France Netherlands
6. Social stability	Applied generally
7. Labor mobility	Sweden, 1957 France, 1960's Federal Republic of German 1960's Austria, 1960's Denmark, 1966 Netherlands, 1970's Norway, 1972
8. Family crisis	Australia, Victoria, 1981

needy, which tended to be the largest families.

As children grow up and leave, large families become small families. But under the housing regulations of most countries, families were not required to vacate subsidized housing as their level of need changed, for example, as the size of family shrank or as the level of income rose; rather they continued to occupy old units, even passing them on to the next generation. In this milieu, after World War II, the International Union of Family Organizations became one of the leading protagonists for a housing allowance system based primarily on the large family rationale. It had an important influence in many countries, especially Belgium, France, Luxembourg, the Netherlands, and Scandinavia.[4]

In the view of the International Union of Family Organizations, the key to providing adequate succor to the most needy was the development of "individual compensation for housing expenses . . . as closely adapted as possible to the circumstances of the household with children."[5] Such a system would ensure a much more effective use of the existing housing stock on the basis of need. As large families shrank and thereby received a smaller housing allowance, they would have an incentive to move to smaller space and to liberate large dwelling units for growing families.[6]

An important corollary was that housing allowances should operate in a national rental housing market organized on the basis of economic rents rather than in a rent controlled market with many different rent levels for equivalent accommodation based on differences in past construction costs and producer subsidy systems. This was essential two reasons. First, it avoided the misuse and waste of h ing subsidies on space for families that had low pric needs or had ceased to be in a needy position, and it enc aged households to move within the market as their hou needs increased or decreased. Second, it stimulated an crease in the supply of rental housing. With the assuranc economic rents, private rental housing investors would have to compete with low, subsidized rents, and thus wo be encouraged to construct new housing.[7]

The original large family hardship model contained other concepts, which, although more or less lost in passage of time, are worth noting. One concerned the mula for calculating the housing allowance. Because family allowance had become a well-established fixture national social policy in many countries, it was maintai that the ratio of the family allowance to nonhousing item the worker's budget provided a ready-made measure need, which could be applied equally well to housing c in the family budget. Thus, if the family allowance equa 20 percent of the nonhousing items in the family budget, housing allowance should equal 20 percent of the hous cost item in the budget.[8] In countries without such legi tion, the International Union of Family Organizations p posed that housing allowances should cover the amount the rent in excess of a reasonable percentage of the fam income, that is, between 6 and 12 percent of income pending on the size of the family and its income.[9]

The other interesting concept was that housing space should be measured in terms of its capacity to accommodate people rather than in square meters of floor space or number of rooms. Accordingly, at its 1954 session, the International Union of Family Organizations adopted the concept of a "housing capacity index" based on two criteria, the number of bedrooms and the total number of occupants of these bedrooms. Thus, a dwelling unit with an index of A 4/6 was an apartment of four bedrooms for six persons.[10] This index was believed to be in the best possible measure of the housing stock's capacity to meet social need.

Concern for the housing needs of large poor families was prominent in the early evolution of housing allowances. Sweden introduced a housing subsidy for families with many children in the 1930's and has continued to expand the coverage until approximately one-half of all families with children now receive a housing allowance. Finland adopted its first housing allowance system for large families in 1941, the system expanding by 1961 to include about 2,000 families.[11] France adopted a housing allowance in 1948 that was payable only to large families which received a family allowance. The Canton of Basle and the city of Zurich in Switzerland launched large family housing allowances in 1963, while Denmark introduced its system for large families and single persons with children in 1964.[12]

Elderly hardship model

A second major category of "most needy" households competing for housing subsidies has been the elderly and the physically handicapped. The old age pension has long been a part of European social security systems; in fact, Chancellor Otto Von Bismark made it a part of the German social insurance system in the 1870's. But while fairly comprehensive in coverage, after World War II European systems were generally deficient in two respects. Pensions were relatively small, and there was little provision for automatically increasing (that is, indexing) pensions to compensate for increases in the cost of living. The systems had been established in an era of price stability, when there was no problem of creeping inflation. As a consequence, a large proportion of the elderly increasingly found themselves in a financial squeeze. Although continued rent controls imposed a brake on the rate of increase in shelter costs, periodic relaxation of rent ceilings clearly intensified rent burdens.

The housing allowance concept offered a cogent solution to this problem. It was a simple subsidy for a well-defined, very needy group. Moreover, because the elderly poor were a rather easily identifiable part of the total poverty problem, governments could provide them with financial relief without opening the floodgate for massive consumer housing subsidies for all the poor.

In the early development of housing allowance systems, the elderly poor often played a central role. In 1948, France established a rent subsidy system for the aged and the disabled living in old apartments. This subsidy was necessary for persons living on fixed incomes, such as pensioners, to offset rent increases which the government began to introduce gradually in the rent ceilings on the old housing stock. After several amendments, this program was completely overhauled in 1971. Since then, it has remained a separate system for the elderly, the physically handicapped, and certain young workers.

In Sweden, where there are three separate housing allowance systems, municipalities provide a special housing allowance supplementing the national retirement pension when the pension is insufficient to provide an adequate dwelling. In 1958, the principles governing the subsidy and its financing became the responsibility of municipalities. As a result, differences in levels of payment prevailed. However, means test rules for determining eligibility now have been established by the National Government. Beginning in 1982, the Government agreed to cover 25 percent of the costs and to coordinate housing allowances for the elderly more closely with the other two more general systems. Among other things, this has involved the imposition of rent ceilings. In 1980, slightly more than one-half of all retired persons received housing allowances under this system.

In 1959, Denmark adopted a rent subsidy plan specifically for those elderly and disabled persons receiving national pensions that were too small to enable them to obtain adequate unsubsidized accommodation. Eligible persons were required to rent subsidized housing owned by the municipality or a nonprofit or charitable housing association. The housing allowance was paid to the owner, not the renter. Two-thirds of total costs were financed by the municipality and one-third by the National Government. The Canton of Basle (Switzerland) launched a similar program for the elderly in 1963. The Belgian housing allowance system is mainly for the elderly. In Australia, the Supplementary Assistance Plan for rental housing for the aged, sole parents, and invalid pensioners was introduced in 1969. Weekly assistance in 1982 was equal to one-half the amount by which rent exceeded $10, with maximum assistance of $10 a week. In December 1982, 86 percent of total pensioners received assistance from this plan.[13]

Finland introduced a housing allowance system for the elderly in 1970 to cover housing costs that were above average. The allowance is paid as a part of the national pension system. The number of recipients rose from 50,000 in 1970 to 179,000 in 1983, accounting for about 50 percent of all housing allowance participants in the latter year.

The elderly hardship model was adopted by five Canadian provinces—British Columbia, Manitoba, New Brunswick, Nova Scotia, and Quebec—in the 1970's and 1980's. The aim was to assist the elderly in keeping their existing housing rather than to rehouse them in new projects. The policy reflected the belief that housing occupied by the elderly generally met acceptable standards and that the problem was one of excessive rent burden.

Elderly recipients appear to predominate in most national housing allowance plans. In France, the Federal Republic of Germany, Sweden, and the United Kingdom, they historically have constituted from two-thirds to three-quarters of all participants. In other words, it may be said that housing allowance systems have tended to become a major auxiliary support to old-age pension systems.

European experience demonstrates that initially restricting eligibility to senior citizens (and perhaps handicapped persons) offers an effective political strategy for introducing a housing allowance system. It clearly targets the system to a widely recognized high priority category. From a social point of view, the elderly are probably the most highly disciplined sector of the population; thus the risks of abuses and problems of administration are minimized. Because elderly demographics are generally well known, it is possible to set the lower eligibility age limit at a level that corresponds to financial resources that the government is ready to make available for such a program. In other words, this approach offers a method for a fine tuning of demand to the current limits of fiscal capacity. Then, if experience demonstrates the practicability of the system, if fiscal capacity grows, and it is believed appropriate, the age limit can be progressively lowered to embrace a steadily larger part of the population.

Rent harmonization model

World War II seriously disrupted the European housing market in many ways, including the rental housing sector. In the face of wartime inflationary pressures, strict rent controls were applied. After the war, governments were slow to decontrol rents, mainly because of the political risks involved. Consequently, major inequities and distortions arose.[14]

First, rent controls created inequities among renters. On the one side, were the longstanding tenants who paid low rents and, on the other side, young couples and war veterans, who paid high rents as recent entrants into the housing market. Second, controls led to inequalities between renters and landlords. Often rents neither covered operating costs, nor yielded a fair return on capital invested. Third, rent controls led to widespread physical deterioration in existing housing. Finally, they were a negative influence on the supply of housing. They were not only an incentive to convert rental housing to owner-occupancy or commercial use and in certain circumstances to demolish the building and sell the land, but also a disincentive for new investment in private rental housing.[15]

Although the aim of European governments generally was the eventual abolition of rent controls, it had become apparent by the 1960's that piecemeal liberalization would not succeed alone. Consequently, a new concept of "rent harmonization" or "rent equalization" emerged, in which housing allowances had a strategic role to play. The objective was to move systematically toward a single unified rental housing market operating as nearly as possible on an economic cost basis. It was believed that, as a result of rising individual incomes associated with postwar national economic growth and inflation, a majority of tenants could afford to pay higher rents. To avoid hardship for those who lived on more or less fixed incomes, a housing allowance or rent rebate would be granted.

This melding of policies was felicitous. It offered a politically acceptable package by eliminating threatened hardship. It introduced an incentive for families to seek housing space in terms of household requirements rather than because of artificially low rents, promoting a more economic use of the existing housing stock. And it offered promise of a fair return on capital to landlords, and thus the capacity and incentive to keep the rental housing stock in a good state of repair.

France appears to have been the first country to link consumer housing subsidies with relaxation of rent controls as an instrument of national policy. In 1948, a modest housing allowance system was introduced to ease the hardship created for persons on fixed incomes who were not able to cope with rent increases.

In 1955, the Federal Republic of Germany adopted its first housing allowance for similar reasons. The allowance was based on the principle that housing expenditures should be kept below 10 percent of the budget for families with very low incomes, rising to 20 percent for those with incomes just under the eligibility limits.

Denmark in 1967 and the Netherlands in 1970 adopted a much more systematic approach. Denmark envisaged the progressive phasing out of rent control over an 8-year period; the Netherlands, over a 10-year period. The assumption was that, during the previous decade, the incomes of most persons had increased sufficiently that they could afford to pay higher rents without exceeding a fair shelter-to-income ratio—in the case of Denmark, 20 percent, the Netherlands, between 13 and 17 percent for families. The housing allowance was an integral part of rent decontrol policy aimed at aiding households with fixed incomes.

Ireland also followed the principle in 1967 with a differential rent policy that adjusted actual rents to the tenant's income and family circumstances, as rents generally were allowed to rise toward a level more in line with the free market.

In the early 1970's, both France and Austria introduced housing allowances to relieve the hardship imposed by increased rents. The French legislation covered only the elderly and the handicapped. The Austrian 1974 law, applying to low-income families generally, also provided that rent increases should be used to cover proper maintenance and, in certain cases, improvement costs. In 1973, the Norwegian Government increased its housing allowance substantially to mitigate individual burdens that might accompany the relaxation of rent controls and the raising of interest rates on existing mortages.

Excessive shelter-to-income model

The European working class has historically not been able to afford decent housing. Workers' pre-World War I expectations regarding a home and a living environment were therefore generally low, except through the help of the government. After World II, however, several factors combined to alter expectations. European economies spurted ahead with rapid technological change, high economic growth rates, and rising individual incomes. During the late 1940's, the 1950's, and 1960's, great strides were made in rebuilding destroyed cities, and in slum clearance. By the mid-1970's, most countries were succeeding in overcoming the global housing shortage and the age of affluence was bringing hope to the common man. As a result, two issues began to receive increasingly greater attention in housing, that is, improving the quality of the housing stock, and relieving the excessive shelter-to-income burden on low-income families.

The housing allowance is an ideal tool for eliminating excessive rent burdens on poor households. Public policy need but do two things: (1) determine shelter-to-income-ratios that various size families can afford, and (2) provide an allowance to cover the difference (or a suitable part of the difference) between actual rents and the maximum percentage of income that families can afford to pay.

This rationale has pervaded several European housing allowance systems, most notably those of Austria, Finland, the Federal Republic of Germany, and the Netherlands. The central principle in the Dutch system is that the tenant should not have to pay more than a reasonable part of his income for rent. In 1978, the standard shelter-to-income ratio for the minimum wage earner, that is, the percentage of income which the tenant was deemed capable of paying for rent, was fixed at 11.2 percent. The Finnish system is similar to the Dutch. In 1983, a three-member household at the minimum wage level was expected to pay 14.5 percent of gross income in rent. The German housing allowance system, covering 1.7 million households or 1 in 16 families in 1978, had as a major objective the reduction of the burden of housing costs on lower-income households. Similarly, in Austria, the Housing Promotion Act of 1968 set up a housing allowance system which focused on the financial burdens which lower income households could reasonably be expected to bear.

Tandem-new construction model

During the 1960's and early 1970's, the increasingly high cost of new construction[16] led inevitably to a growing gap between rents for newly built housing and rents of the older housing stock for roughly equivalent accommodations. One of the dire consequences of this gap was that, in spite of persistent housing need, by 1974 and 1975, a large number of dwellings, especially in Denmark, the Federal Republic of Germany, the Netherlands, Sweden, and Switzerland, were remaining vacant for well over a year because rents were too high.[17]

In this situation, another housing allowance rationale emerged, which will be called the tandem-new construction model, that is, a housing assistance policy which works as a complementary arm with the national policy on new housing construction. In essence, the housing allowance became a tool to facilitate the renting of new, modern, high-cost apartments to a clientele who could not otherwise afford them.

Norway was a pioneer. In 1967, a National Commission was appointed to design a more comprehensive subsidy system. One of its central recommendations was that subsidies should be paid only to households living in recently built dwellings; these were the most expensive because of high building costs, interest rates, and land costs. But the Commission also recommended that subsidies be paid only for the first 10 years after completion (compared to the then existing 15-year period) and that during that period subsidies should be gradually reduced. The Commission's rationale relating to new construction was generally accepted in the 1972 housing reform.

An interesting variation of this model has been developed in Sweden. In 1966, 43 percent of families with children were living in overcrowded conditions, as legislatively defined, that is, more than two occupants per room excluding kitchen and living room. Sweden undertook a huge effort to upgrade the quality of housing, using the housing allowance as a means of helping large, low-income families to obtain "modern and sufficiently large dwellings." The new system provided an incentive to occupy new, expensive, large dwelling units by offering a higher percent of rent subsidy for the more expensive units, that is, 40 percent, than for the less expensive units, which received a housing allowance of only 30 percent of the rent.

The tandem-new construction rationale also became an important element in the housing allowance systems of France and the Netherlands.

Social stability model

European societies have traditionally put emphasis on social stability. In part, this derives from the class structure inherited from the past, which tended to be threatened by the instabilities associated with social change. In part, the stability has its roots in the strong family, neighborhood, and religious orientation of European urban systems. It may also be partly attributable to the old perception that the size of the national economic pie was more or less fixed and that, consequently, there were fairly well-defined constraints on one's economic well-being. (Such beliefs were common until the unprecedented economic growth following World War II began to belie them.)

In this setting, the eviction of a household because of inability to pay rent is regarded as a serious threat to social stability. It is disruptive to family life and a loss to the neighborhood. To diminish this threat, most European countries have built into the law considerable tenure rights for renters.

To reduce still further the risk of eviction, a logical next step was to bolster the ability to pay of economically weak households by providing a housing allowance. The elderly have perhaps been among the most vulnerable to circumstances beyond their control. The rent-paying capacity of persons on fixed incomes is rapidly eroded by inflation. Most of the animus of early housing allowance plans for the elderly, noted previously, appears to have been rooted in the concern for social stability. The financial crunch was forcing elderly persons to give up their homes and this was regarded as highly inimical not only to the welfare of those displaced but also to the very core of society itself. There is in this respect, therefore, an overlap between the social stability model and the elderly hardship model.

Similarly, low-income families, already suffering hardship from their economic status, are highly vulnerable to forces beyond their control, such as unemployment and depression. To a considerable degree, therefore, housing allowances in a number of countries have been designed not to improve housing conditions *in situ,* nor to enable households to shop around for alternative accommodation, but merely to strengthen the ability of financially weak households to keep the housing they have.

Labor mobility model

The motif of the labor mobility model is in contrast with that of the social stability model. It is the response of a housing market long under the heavy hand of rent controls.

As noted earlier, there is a strong incentive for households to continue occupying large, low-rent, centrally located apartments long after their housing requirements—as determined by the size of family—have changed, because most alternative smaller units are recently built and, therefore, have much higher rents. Socially, this condition is a gross misallocation of housing space. Economically, it constitutes a serious brake on the rate of national economic growth by preventing the labor force from moving easily as economic growth and job markets beckon. The housing allowance has helped remedy this situation to some extent.

The simplest way to use housing allowances as an instrument for promoting labor mobility is to restrict participation to households living in the most recently built apartments, which by definition were more costly to build and are thus let at the highest rents. All countries have encountered increasingly difficult problems in finding tenants, particularly among low- and moderate-income households, to contract for these high-rent dwelling units. Going back to its early experience, Sweden limited its housing allowance system established in 1947 to dwellings that were erected or converted after December 1947. Norway restricted its 1972 housing allowance plan to housing built after 1962. The Dutch housing allowance system before 1975 was available only to households living in rental accommodation built after 1960. Two Austrian provinces (Tryol and Vorarlberg) and the country of Denmark have likewise provided that households would be eligible only if their accommodation was built after a specified date.

In 1966, the housing problem became a central issue in Denmark. In a celebrated Housing Pact worked out by the major Danish political parties, one of the major objectives agreed upon was to encourage greater mobility within the housing stock by means of rent harmonization and the introduction of housing allowances for tenants. Similar considerations have also been prominent in French and German housing allowance policy.

Another, perhaps more indirect, way that governments have applied the labor mobility model is by establishing high standards of physical construction and housing amenities as a condition for coverage by the housing allowance system. In many countries, only postwar or even more recent construction—and thus the most expensive rental dwelling units—can meet such requirements.

Again the rationale is similar. Rent controls and the basing of rents on postwar construction costs have created large rent differentials that may not be representative of real differences in housing habitability. Much of this new postwar construction has been in reponse to economic growth needs, but rent differentials have had the unfortunate result of discouraging mobility in the labor market. Encountering difficulties in letting such high quality, high-rent housing units, governments have developed housing allowance systems as a means of reducing the rent burden and providing an incentive for greater labor mobility.

A number of governments, including those of Denmark, France, the Federal Republic of Germany, the Netherlands, and Sweden, have gone further and used other types of housing assistance to promote labor mobility. For example, in 1975, the Netherlands adopted a rent readjustment grant to assist households that were capable and desirous of living in better accommodations, but who were intimidated by the sudden increase in rent and the burden of moving costs. Three types of tenants were eligible: those leaving an older, cheaper unit for a newly built, higher rent unit (the "moving-up process"); those leaving a slum dwelling for a higher rent unit ("slum clearance"); and those whose rents had been increased because their current accommodations had been modernized ("housing improvement").

Providing the difference in monthly rent was at least $11.86, the Dutch rent readjustment grant covered 75 percent of the difference the first year, 50 percent the second year, and 25 percent the third year. In 1982, the grant was lowered to 60 percent the first year and to 40 percent the second year. However, certain ceilings were set. The tenant's annual 1975 taxable income could not exceed $11,860 and the monthly rent of the vacated dwelling could not be more than $98. In addition, a special grant of up to $1,383 was made available to help cover removal and refurnishing costs for households experiencing major housing improvements or slum clearance and for elderly people moving from low-rent dwellings to smaller, more expensive units or to nonself-contained accommodation.

Family crisis model

Frequently low- and moderate-income families are confronted with temporary household crises, such as loss of job or ill health of the breadwinner(s), or desertion of the family by the husband or wife. If the family must move because of nonpayment of rent, this imposes a heavy burden on the household and the community, for example, in the loss of local friends and support services and disruption in children's schooling, in addition to the costs of moving. In contrast, if temporary assistance can be provided, the family is generally able to cope.

Probably in most countries this kind of crisis tends to be dealt with through some form of public assistance. But in 1981, Victoria Province in Australia embarked on an interesting pilot rental subsidy program.[18] The objective is to provide emergency financial support to enable families to remain in their existing situation. The subsidy is temporary and is paid out for a maximum period of 12 months. This rationale could be considered as a subset of the social stability model, but because it is sufficiently imaginative in its social and psychological design it is included as a separate model.

A related program, the Mortgage and Rent Relief Scheme, was adopted by the Australian Federal Government in 1982 to provide assistance to "crisis" cases of people in rental difficulties. The Commonwealth provided the States with $20 million (Australian) per annum on a matching basis for 3 years with the intent of providing short-term assistance (about 12 months) until either the crisis was resolved or a longer-term solution was found. Relief was provided in advance as quickly as possible, the first payment being made within 2 weeks after registration.[19]

IN FOREIGN EXPERIENCE, the housing allowance has proved to be a highly flexible and versatile tool of national policy. Not only has it been an effective means for directly reducing excessive rent burdens on low-income families, especially the elderly, the physically handicapped, and large families, but it has also provided powerful support in implementing other important national social and economic objectives. It has been an instrument for harmonizing rents and in developing unified rental housing markets. It has complemented producer housing subsidy programs in helping to maintain markets for new housing, and has strengthened social stability by assisting financially weak households to keep their housing. Finally, it has been a useful means of stimulating labor mobility needed for national economic growth and the development of new job markets. ☐

Short-time compensation: assessing the issues

FRANK W. SCHIFF

Since 1978, 10 States have adopted legislation to permit the voluntary use of short-time compensation—that is, work sharing as an alternative to layoffs, combined with the payment of partial unemployment insurance benefits to help compensate employees for their lost work time. The available surveys all indicate that where these programs have actually been used, they have generally been well received by both employers and employees. At the same time, overall usage of short-time compensation has thus far been quite limited, particularly among larger firms.

How short-time compensation will fare in the future will no doubt depend importantly on how actual experience with short-time compensation is evaluated. This paper examines some of the key questions that need to be addressed in assessing the impact of short-time compensation; reviews to what extent they have been answered by recent evaluation studies; and discusses the relevance of this information for the future. I shall draw particularly on two studies that have just become available: the large scale *Evaluation of Short-Time Compensation Programs* prepared by Mathematica Policy Research, Inc. for the U.S. Labor Department[1] and the case study prepared by Bennett Burgoon and Robert D. St. Louis for Motorola[2]—the firm which has been the largest single user of short-time compensation so far—that assesses the use of short-time compensation in Motorola's Arizona operation during 1982–83.

Work sharing versus layoffs

My first issue is whether short-time compensation use in cyclical situations implies higher costs for the unemployment insurance system than outright layoffs. This was the central focus of the Mathematica study.

One aspect of this question relates to administrative costs. Mathematica found that these costs were greater under short-time compensation than under regular layoffs. But this finding reflected early experience with the program in only one State. The Mathematica study notes that with more experience, administrative costs under short-time compensation may well be significantly reduced, including having employers file claims for short-time compensation users *en masse*. If one also considers that there will be savings for the Employment Service because it does not have to provide job search assistance and other services associated with regular layoffs, then there is a possibility that net administrative costs with short-time compensation might prove less than with regular layoffs.

A far more important issue is whether the total number of unemployment insurance-compensated hours of unemployment—and the associated unemployment insurance benefit costs—are likely to be greater with short-time compensation programs than with outright layoffs. Surveys of both employers and employees conducted in 1982 by the California Employment Development Department suggested that total work time losses under short-time compensation were significantly less than under layoffs. On the other hand, various simulation studies prepared by the Department produced exactly opposite results.[3] However, both types of assessment suffered from important methodological shortcomings. The Mathematica study, which covered work sharing experience in California, Arizona, and Oregon from mid-1982 to mid-1983 and used sophisticated econometric techniques, sought to avoid such shortcomings primarily by relating the experience of firms using short-time compensation (often side-by-side with direct layoffs) to that of a comparison group of firms that presumably faced similar economic circumstances.

Mathematica's principal finding was that for firms using short-time compensation, total hours of compensated unemployment (including *both* regular unemployment insurance and short-time compensation benefits) were larger than for

---

firms relying solely on direct layoffs—on average approximately 11 percent. However, in Oregon, total hours of compensated unemployment were almost identical for the two groups. In California, total compensated unemployment for firms using short-time compensation was said to exceed those of the comparison group by 29 percent, while the differential in Arizona came to 12 percent. Another way to describe the Mathematica results is in terms of *marginal* effects. Thus, the study showed that in Oregon, each hour of compensated unemployment under short-time compensation substituted for an hour of regular layoffs. For California, on the other hand, the study produced the extraordinary result that there had been virtually no substitution. The substitution rate for Arizona was about 50 percent.

On the basis of simulations that used these various results as inputs, the study also concluded that unemployment insurance benefit charges for firms using short-time compensation can be expected to be higher than those for similar employers who do not and that this is likely to impose a net drain on the Unemployment Insurance Trust Fund in the short run. However, these negative impacts were expected to be significantly reduced over time by more complete experience-rating of short-time compensation benefits and by revenues gained from special short-time compensation surtaxes.

There is a major question in these studies as to whether users of short-time compensation and non-user comparison employers actually faced similar economic circumstances. Only three primary characteristics were used in selecting comparison group firms: industry classification (according to three-digit Standard Industrial Classification codes); employment size; and the unemployment insurance tax rate. The unemployment insurance tax rate has little relevance to current economic conditions. The relatively broad industry classifications used did not automatically assure that firms in the comparison groups were subject to the same degree of economic stress as those which used short-time compensation.

One specific indication of such stress would have been evidence that these firms were laying off people. In fact, however, a significant number of comparison group firms showed no layoffs. If there were conclusive evidence from other sources that the two sets of firms faced similar economic conditions, the exclusion of firms with no layoffs from the comparison group might be justified, but this was clearly not the case in this instance. When one *excludes* firms that made no layoffs from the comparison group, the excess in total hours of compensated unemployment for firms using short-time compensation over those in the comparison group falls from 11 percent to 7 percent. Moreover, when the figures are adjusted to take account of delayed impacts of work sharing in the first two quarters after the year covered by the study, the differential almost disappears.

Even with these adjustments, the Mathematica study still suggests that total hours of compensated unemployment were larger for short-time compensation firms than for the comparison group firms. But this qualitative result, too, is open to question when other aspects of the Mathematica study are considered. Thus, there are other indications that short-time compensation participants may in fact have faced more severe economic conditions than comparison group employers. The report indicates, for example, that short-time compensation firms were significantly more likely to have had financial losses in fiscal year 1982 than comparison group firms. Also, in California, short-time compensation employers were more heavily concentrated in durable manufacturing than comparison group employers.

Moreover, the basic finding for California—that use of short-time compensation essentially did not substitute for layoffs *at all*—strikes me as totally implausible. Since short-time compensation firms had to submit affidavits indicating that short-time compensation represented an alternative to layoffs, one would have to believe that all of these affidavits were 100 percent inaccurate. Even less credible is the implication that the unions involved would go along with a program that involved wage losses for *all* their members without any compensating gain in terms of reduced layoffs.

An additional problem is posed by the fact that the Arizona part of the study excluded Motorola's operations, which accounted for approximately 40 percent of the employees covered by short-time compensation in that State. This was done on the ground that a comparison group employer of equivalent size could not be found. It raises a major question, however, whether the overall finding for Arizona—namely, that short-time compensation firms used more hours of compensated unemployment than comparison firms—would have held if Motorola had been included in the study. This is a particularly pertinent question because Motorola's study of its experience with short-time compensation indicated that when the units surveyed went on a 4-day week, a significant number of employees did not draw unemployment insurance for the fifth day. Hence, overall unemployment insurance costs, at least under this firm's work sharing program, may well have been *less* than if regular layoffs had been utilized.

What does all this add up to? My overall assessment is that while the Mathematica study has provided useful insights into the measurement problems in this area, its findings with respect to the likely impact of short-time compensation programs on the Unemployment Insurance Trust Fund are beset by so many uncertainties that they can by no means be regarded as conclusive. In my view, this applies even to Mathematica's *qualitative* conclusion that short-time compensation programs are likely to entail greater use of compensated hours of unemployment than outright layoffs.

Structural adjustments and net costs

A second issue relates to the need to distinguish between short-time compensation in cyclical situations and as part of structural adjustments—that is, as a device to ease the transition toward permanent layoffs. Mathematica found that the firms it studied used the program only to deal with temporary declines in demands for labor. These findings, however, relate to a period of unusually severe cyclical downturn. More recently, problems of structural unemployment and permanent dislocation of workers have gained in relative importance, particularly as a result of sharply rising competition from imports. Hence, the possible use of short-time compensation in such structural situations will bear close watching.

A third area for further investigation involves the impact of short-time compensation on the net costs of employers. The Mathematica study provides some useful perspectives on this issue through the use of employer surveys and some simulations. Another way to approach this subject is through case studies. In this connection, I find the case study just issued by Motorola (the firm which has been the strongest advocate of short-time compensation) of special interest. Motorola utilized work sharing in its Arizona nondefense semiconductor products operations during 1982 and early 1983. The total number of employees participating in these short-time compensation plans came to more than 9,000. On the basis of a detailed examination of costs and benefits of work sharing in six representative departments, the study concluded that short-time compensation had resulted in a sizable net saving for the firm, compared with layoffs. Motorola also concluded that future use of short-time compensation is likely to result in significant net savings for the company over periods of up to 6 months and would, in most cases, probably produce net savings for at least 1 year.

The savings cited in the report were based on costs and benefits that could be directly quantified. The company indicates that the savings from work sharing would be larger if one considered factors that are harder to quantify, such as higher morale in the absence of layoffs, the avoidance of "bumping" and other disruptions of established production processes, and the competitive advantage the firm gained by being able to respond quickly to pickups in demand during the recovery phase with an established, fully trained work force.

These results, of course, are unique to Motorola's specific situation and may not necessarily hold in other cases. The study is nevertheless very valuable and a useful model for similar efforts because of the precise way in which it pinpoints specific elements of costs and benefits from the use of short-time compensation.

Affirmative action results

A fourth issue is whether short-time compensation has had favorable "affirmative action" results. A major argument for using work sharing as an alternative to layoffs has been that it would preserve the jobs of minority group members, women, and younger workers who are typically viewed as among the "last-hired" and the "first-fired." With short-time compensation, employees in these categories do not have to be laid off and potential conflicts between seniority rules and affirmative action requirements are avoided.

Surprisingly, the Mathematica study did not find that these groups cited fared better under short-time compensation than with direct layoffs. This, incidentally, was also the finding of the California study. As Mathematica has suggested, a more detailed look at the available data seems desirable to help determine how this counter-intuitive result can best be explained. One possibility is that firms using short-time compensation have been particularly progressive in their labor relations and that the groups cited were not disproportionately represented among the "last hired" by these firms. A contrasting explanation would be that members of such groups had been selectively dismissed prior to the adoption of short-time compensation by the firms. Mathematica did not find evidence for this in its study, but future studies should be alert to this possibility.

If it should turn out that short-time compensation programs do have positive affirmative action results, questions might be raised about the desirable length of such programs. At present, the time period for which particular employees can stay on the program usually does not exceed 26 weeks. If there is a severe recession that lasts longer than this, should the period of eligibility be extended to include the full period of the recession? If the program ends in the middle of a recession, the "last-hired" would still be the "first-fired." One way to deal with this problem would be to permit longer-than-normal periods of short-time compensation use if national or local area unemployment rates, or both, remain unusually high for prolonged periods.

AS MORE INFORMATION about the issues raised here becomes available, the case for adopting additional administrative requirements under the short-time compensation program may also become stronger—for example, to increase the likelihood that short-time compensation will, in fact, be used as an alternative to layoffs; to allow clearer distinctions between cyclical and structural adjustments; or to permit more extended use of work sharing in prolonged recessions. ☐

Work sharing programs: an evaluation of their use

Stuart Kerachsky, Walter Nicholson,
Edward Cavin, and Alan Hershey

Among the most innovative changes to basic unemployment insurance since its inception is short-time compensation. The programs allow workers to receive partial unemployment benefits in the event that they suffer even moderate reductions in their work hours, as long as those reductions are expected to be temporary. Employees who have their work time reduced by, say, 1 day per week might be eligible for one-fifth of their weekly unemployment insurance benefit amount. This policy differs from previous unemployment insurance regulations, under which such workers would typically be ineligible for any benefits. It is generally believed that broadening the conditions under which unemployment insurance benefits may be paid will help reduce the "pro-layoff" bias of unemployment insurance and, instead, encourage employers to adopt reduced-hours strategies during periods that necessitate reducing employment levels.

This report is based on research on short-time compensation programs undertaken in response to Section 194 of the Tax Equity and Fiscal Responsibility Act of 1982. Through the Act, Congress recognized the growing number of States that have adopted short-time compensation programs as part of their overall unemployment insurance systems, and raised many important questions in response to those State efforts.[1]

The short-time compensation experience we will refer to occurred from mid-1982 to mid-1984 in the three States that have operated programs for the longest period of time: California, Arizona, and Oregon. The study focused primarily on the behavior of employers, although some issues that pertain more directly to employees were addressed with employee data aggregated on a per-employer basis.[2]

Before results of the study are discussed, three important limitations of its overall design should be stressed. The first is that the study involved only three States, each of which exhibited very low levels of short-time compensation use. The implication is that it is extremely difficult to generalize from the experiences of these States to other States that are using short-time compensation or that might use it in the future. The second is that the study did not collect data directly from employees. Thus, many issues that pertain to the attitudes and overall well-being of workers could not be addressed directly. However, evidence on some of these issues was available from information provided by employers and through unemployment insurance records. The third is that the use of a comparison-group methodology may be problematic. Both the operational status and the limited use of the work sharing programs in the study's States precluded an experimental design that would have assigned firms *randomly* to short-time compensation and control groups. Hence, it is possible that uncontrolled-for differences in characteristics among firms that used short-term compensation, and those that did not, may have contributed to some of the observed differences in outcomes.

Work sharing versus layoff

As noted, the primary purpose of short-time compensation is to provide firms with an alternative to layoffs during temporary downturns in their demand for labor. Many of the potential social benefits from work sharing (such as reduced labor turnover costs or increased work force productivity) derive from the ability of the program to encourage firms to substitute hours reductions for layoffs. To examine this substitution, we chose to focus on the hours spent on regular unemployment insurance and on short-time compensation by workers in our sample firms. These data were normalized by total hours employed in the fiscal 1982 base period, so as to create measures of the percentage of work time spent in these two forms of compensated unemployment. Although measuring layoffs and hours reductions with data on compensated unemployment poses some conceptual disadvantages, we believe that they are largely outweighed by the enhanced accuracy of data on compensated unemployment (because the data come from administrative records) and by the relevance of compensated unemployment to various issues of unemployment insurance financing. These data were used to examine differences in the percentage of work hours spent on compensated unemployment between firms that were short-time compensation users and those that did not participate in the program.

Although the findings exhibited fairly large State-by-State differences, three major patterns were apparent. First, participation rate in short-time compensation was very low: generally less than 1 percent of all employers in the sample States participated at any point in time, and less than 1 percent of unemployment insurance benefit claims were for short-time compensation. Second, the average firm in the short-time compensation sample appears to have continued using layoffs as the primary method of work force reduction. In no State did work sharing represent more than 25 percent of total hours on compensated unemployment among firms that used the program. Third, although evidence clearly suggests that short-time compensation did reduce layoffs (as measured by the reduced receipt of regular unemployment insurance), this substitution does not seem to have been on an hour-for-hour basis. In all of the States, firms that used short-time compensation experienced some net addition to total hours of compensated unemployment (both regular unemployment insurance and short-time compensation), although this addition was quite small in Ore-

---

Stuart Kerachsky is a senior economist, Mathematica Policy Research, Inc., Princeton, NJ; Walter Nicholson is a professor of economics at Amherst College, Amherst, MA, and a senior fellow at Mathematica; and Edward Cavin is a senior economist and Alan Hershey, a senior policy analyst, both at Mathematica. The title of their full IRRA paper is "An Evaluation of Short-Time Compensation Programs."

gon. Hence, the empirical results suggest that the actual work force-adjustment strategies adopted by firms under short-time compensation might be quite varied and complex.

The large State-by-State differences in the apparent response to short-time compensation use posed a number of questions that could not be answered satisfactorily. Whether they represented differences caused by how the program is administered, unmeasured differences among the types of firms in the various State samples, or some undiscovered methodological problem in these comparisons could not be determined conclusively given the small number of States involved and the limitations inherent in a comparison-group methodology. However, broadly similar results were obtained through a wide variety of econometric methods.

A number of other topics pertaining to layoffs and short-time compensation use are investigated in the technical report.[3] Perhaps the most interesting finding from these additional investigations is that work sharing appears to have had no discernible effect on the demographic composition of layoffs undertaken by participants. That is, contrary to what has been hypothesized about the program, short-time compensation did not seem to have major "affirmative action" advantages for newly hired minority and female workers.

Unemployment insurance trust fund

Concern that widespread use of short-time compensation might have a negative impact on unemployment insurance trust funds has made many States cautious in adopting such programs and has prompted them to include in their laws special surtax provisions for firms that use the program. This concern appears to have arisen from two sources. The first is the possibility that workers who are placed on short-time compensation may have somewhat higher wages and, hence, higher weekly unemployment insurance benefit amounts than do workers who may have been laid off. Second, if short-time compensation encourages more compensated unemployment than would have occurred under a layoff-only strategy (as our results suggest), benefit payments to workers in firms that use short-time compensation may also increase.

The study results tended to support these presumptions. In all of the States, mean per-employee benefit charges (for regular unemployment insurance and short-time compensation) were significantly higher in the samples of firms that used short-time compensation. About half of the differences appear to be related to the higher unemployment insurance benefit levels for which short-time compensation recipients are eligible, and the other half can be attributed to additional amounts of compensated unemployment.

However, we also found that firms which participated in work sharing tended to have greater increases in their unemployment insurance tax rates over the study period than did otherwise similar firms who did not use the program. Although developing a precise model of how these extra tax collections should be netted against the additional benefit amounts paid was beyond the scope of the project, it was possible to provide a rough, qualitative assessment. In the short run, it is likely that short-time compensation imposed some drain on the unemployment insurance trust fund. Lags in the operations of the States' experience-rating formulas make it unlikely that the extra benefits payable under short-time compensation can be recouped in 1 or 2 tax years. Over the longer term, however, the picture is quite different. Because short-time compensation benefit charges under most of the States' current surtax provisions are more effectively experience-rated than are regular unemployment insurance benefit charges, it seems likely that any extra benefit charges would be fully recouped in the long run. Hence, concerns about the fiscal impact of work sharing might properly be focused on ensuring trust fund adequacy during temporary downturns, because the longer term solvency of the system would not seem to be imperiled by short-time compensation programs if surtax provisions are included in State laws.

Administration of the program

In adopting short-time compensation amendments to their basic unemployment insurance laws, all States attempted to restrict the concept's use to its intended purpose of substituting for layoffs during temporary downturns. In our study, we catalogued a wide variety of these provisions, and attempted to establish their effectiveness. The following general picture emerged: programs experience some startup problems but, on the whole, seem susceptible to careful monitoring and direction. We did find that some of the specific provisions of State laws do not appear to effectively ensure adherence to the basic goals of short-time compensation. (For example, constraints on minimum required work reductions do not seem to restrict minimum hours reductions to at least one averted layoff.) But these shortcomings seem relatively minor, and, in any case, the small number of States in the analysis precluded any quantitative assessment of the impacts of variations in such provisions.

In terms of unemployment insurance administrative costs, work sharing has both advantages and disadvantages relative to an equivalent work force reduction that involves only layoffs with the associated unemployment insurance collections. Initial claims-filing costs are lower under work sharing (because eligibility determination is simpler), and cost associated with unemployment insurance "work test" monitoring do not arise. However, relative to an equivalent level of layoffs, short-time compensation entails processing a much greater number of weekly benefit claims. Our analysis (which was constrained by a relatively meager amount of administrative cost data) suggested that, under current circumstances, the costs associated with the greater volume of claims tended to dominate the lower per-claim costs. However, in interpreting this conclusion, it is important to keep in mind the relative newness of short-time compensation programs. It is quite possible that the administrative cost disadvantages of them may decline over time as experience with the programs accumulates. ☐

FOOTNOTES

[1] The questions focused on the effects of short-time compensation on contemporaneous and subsequent layoffs, unemployment insurance tax rates, the integrity of the unemployment insurance trust funds, and the net benefits to the various affected parties.

[2] The analysis was based on survey and unemployment insurance records data covering 1,050 firms spread across the three States. Approximately half of the sample had used short-time compensation during the study period, and the other half did not. Nonusing firms were carefully matched to the program sample on many observable dimensions, and the actual analysis was based on regression techniques that controlled statistically for possible remaining sample differences.

[3] Stuart Kerachsky and others, "An Evaluation of Short-Time Compensation Programs: Technical Report" (Mathematica Policy Research, Inc., Princeton, NJ, December 1985), prepared for the Employment and Training Administration, U.S. Department of Labor.

Short-time compensation: the AFL–CIO perspective

JOHN ZALUSKY

In 1975, the proposal that shorter workweeks be financed through the unemployment trust funds was cautiously but favorably received by AFL–CIO President George Meany, who wrote to Lillian Poses that the Federation's " . . . general view is in favor of the plan as long as it remains voluntary and safeguards are included in state legislation to protect all parties."

As high unemployment continued, States began cutting unemployment benefits and it became clear that using trust funds to pay for a reduced workweek would mean worse hardship to those totally unemployed. And because benefits had lagged far behind wages, it looked as though senior workers in higher wage classifications would lose a higher share of their incomes, and not just for a few weeks, but for months or years.

Blindness to these threats to well-paid workers with secure jobs on the part of those who continued to promote work sharing as a "win-win" solution to layoffs eroded support among labor leaders. Repeated citations of the great success of German and Canadian experiments with work sharing turned out to be overstated, if not misrepresented. Both the German and Canadian counterparts of the AFL–CIO, the Deutscher Gewerkschafts bund Bundesvorstand (DGB) and the Canadian Labour Congress (CLC), reported problems and shortcomings that made it clear that foreign experiences were irrelevant and nontransferable to the American scene. The AFL–CIO then set about formulating its own concept of how short-time compensation could be made to work in the United States.

While discussions were going on within the AFL–CIO and jointly with the Department of Labor, the California legislature adopted the experimental short-time compensation law which has been extended three times since 1978 and will run through 1986. Although the California AFL–CIO neither supported nor opposed the Shared Work Unemployment Compensation bill, the plan proved more positive than might have been expected in that time and place, and a number of labor leaders strongly supported its passage and extension. Many workers gained from the bill under existing contracts—about 20 percent of the agreements allowed employers to reduce the workweek before resorting to layoffs. Previously, when employers exercised this option, considerable numbers of workers lost income without being able to qualify for unemployment compensation. In meeting this need, California's shared work bill opened the way for further development and experimentation and helped lay the foundation for the executive council's resolution of August 5, 1981, endorsing the concept of short-time compensation and outlining the conditions needed to make the concept's promise a reality.

First, the council said that short-time compensation must not be viewed as an alternative to active government programs to stimulate employment opportunities and the economy. This is vital because work sharing redefines employment while creating no new employment opportunities. This tends to hide a large part of the unemployment problem by inflating the statistic, "Working part-time for economic reasons." In 1985, there were 5.4 million workers in this category, and although it is better than being unemployed, it reflects the failure of our economy to provide full employment. This general concern is strongly shared by the German and Canadian labor movements.

Secondly, the needs of those completely unemployed must be given the highest priority. If short-time compensation increases costs to the unemployment insurance fund, as it certainly may, legislators face the options of either reducing benefits to the unemployed in one way or another or of increasing revenue. And in today's political climate, it is nearly impossible to raise revenue for social needs. This approach—of looking at the costs to the fund—regards unemployment insurance and short-time compensation as a closed system. The meaningful cost-benefit analysis would fit work sharing into the total cost of unemployment to society.

Although the benefits of short-time compensation warrant increasing the funds available for this purpose, well-meaning supporters want to sell it to the employer as a cost-free benefit. This is unrealistic. Work sharing is in the best interest of the States and local governments, most workers, and many farsighted employers. But to do the job well will require additional funding. A fair-cost analysis that looks at all of the costs to State and local governments for unemployment, including lost taxes, the cost of support

---

John Zalusky is an economist in the AFL–CIO, Washington, DC. The title of his full IRRA paper is, "Labor's Interest and Concerns with Short Time Compensation."

systems, and the wasted worker's skills, will demonstrate the value of a strong, well-funded program.

Overall, the AFL–CIO supported the short-time compensation concept as a tool in dealing with the multiple consequences of unemployment, but not as a no-cost or even low-cost, "win-win" solution. The problem is that too few employers support it or use it at all, as long as they can get most of the benefits of work sharing costs by just transferring the burden to workers. Workers should be entitled to short-time compensation, through unemployment insurance or some other funding, any time the workweek is reduced due to a lack of work. Absent this, work sharing will only be used by few forward-looking employers, willing to sign up for the program and then after they have laid off the more easily replaced workers.

As the executive council resolution stressed, the AFL–CIO wants assurance that firms that use the concept do not lay off the recently hired and less-costly-to-recruit workers first, that is, women and minority group members.

This issue has been the hardest to deal with, and yet it would seem to be a fairly easy one on which to get support. In discussing this issue prior to passage of the Tax Equity and Fiscal Responsibility Act of 1982, the AFL–CIO sought a provision in the act requiring that employer progress toward Equal Employment Opportunity goals would not be reduced by layoffs prior to application for short-time compensation. Employers objected strongly on the grounds that it would encourage "EEOC fishing expeditions." And, surprisingly, the civil rights groups which the AFL–CIO generally works with were willing to drop the issue on assurance that short-time compensation by its nature would be "helpful."

The result was the present language in Section 194(d)(3) of the Tax Equity and Fiscal Responsibility Act of 1982, which suggests to States that their laws limit participation to employers who have not reduced their work force 10 percent by layoff in the previous 4 months. At the time, it seemed that this language would protect the newly hired youth, minorities, and women. This does not seem to be the case. Rather, it seems to have limited employer participation with little or no help for the newly hired.

The AFL–CIO and other supporters of short-time compensation often complain that employers fail to adopt the concept. Some feel that the low usage is due to employers' lack of knowledge. The Federation is sure this is not the case. The basic options to the employer are not work sharing versus layoff—they are layoffs with unemployment insurance, work sharing without unemployment insurance for their workers, and short-time compensation with unemployment insurance for their workers, or a combination of these options.

The evidence that too few employers use the short-time compensation concept is no surprise. The least cost options to many employers are to reduce the workweek, resort to rotating crews, simply shut down for a week, or require employees to use earned vacation time—all of which avoid adverse unemployment insurance experience ratings and increased costs—and then layoff the most easily replaced workers.

From March 1980 to March 1985, private-sector costs for unemployment insurance increased 15 percent. All other factors remaining equal, there has been a growing incentive for employers to avoid unemployment insurance increases and short-time compensation, just as they have avoided other labor costs. Therefore, if work sharing is to be useful to protect employment opportunities, it should be elective to employees, not employers. And this leads to the final two points in the AFL–CIO Executive Council Resolution, that workers participate voluntarily and that the income replacement be two-thirds of their individual gross pay for each day lost. Most workers would be willing to share their employment with others with lesser entitlements if the hardship is not too great in amount or in time.

Economic need can be just as great among individual workers with longer years of service as to those new to the work relationship. Some senior workers are paying college tuition. About 12 percent have pensions based on their last few years of work. Others have their homes paid for, their children have finished school, and they may well relish preretirement time off.

Elective work sharing is far more acceptable and a lot less devisable than any unilateral decision by the employer or even by a majority of workers in a local union. Thus, rather than force short-time compensation on senior workers, the far better solution is to attract them to it by a respectable income replacement level and maintenance of benefits. The two-thirds replacement rate of individual gross income is also somewhat less than that for the Steelworkers and Autoworkers Supplemental Unemployment Benefit. But the supplemental plan showed that senior workers volunteered for layoff when the income replacement rate was over 80 percent and benefits continued. The short-time compensation replacement rate could be lower, because these higher paid workers will still be working a good share of the week.

California, Arizona, Oregon, Washington, Florida, Maryland, and New York have adopted short-time compensation, and Kentucky, Ohio, Pennsylvania, Illinois, Wisconsin, and New Jersey have considered the concept. The AFL–CIO supports the concept, but delivery on a no-cost, low usage and low benefit basis has been far short of the promise of full employment made by this Nation.

The workers and their unions that have had experience with short-time compensation are pleased with the program and support its improvement as a part of the unemployment insurance concept. But if the full value of the concept is to be achieved for the community, the State, and the Nation, workers must be entitled to short-time compensation when the workweek is reduced, and the funds must be available to maintain benefits and wages while providing decent benefits for those who are totally unemployed. □

A new leading indicator: workers recently laid off

Geoffrey H. Moore and John P. Cullity

Layoff rates have long been used as leading indicators in business cycle analysis. The layoff rate in manufacturing was initially selected as a leading indicator of business cycles in 1960.[1] In 1961, it became 1 of 12 leading indicators published by the Bureau of Economic Analysis in *Business Conditions Digest*. The rate was derived from the labor turnover survey of manufacturing establishments, conducted by the Bureau of Labor Statistics and discontinued at the end of 1981. BEA subsequently replaced layoffs with initial claims for unemployment insurance.

Prior to 1967, the Current Population Survey collected data on laid-off workers on a very limited basis and only indirectly. This group included only those persons who were neither working nor looking for work, but responded that they had a job from which they were temporarily laid off and expected recall within 30 days. Since 1967, nonworking survey respondents have been asked directly whether they were on layoff. These workers are counted as unemployed regardless of their job search activity and form a subgroup of the job losers category. Further, workers on layoff are classified by the number of weeks since they were laid off.

At the Center for International Business Cycle Research, we used the number of all job losers on layoff, together with temporary layoffs prior to 1967, as a component of our leading employment index.

Recently, we observed that a better leading indicator could be obtained from data on *recent* "job losers on layoff," rather than all workers on layoff. The recent jobless consist of those who were laid off within the last 5 weeks and are still unemployed at the time of the household survey. This group would seem to correspond closely to those included in the reports by employers on the number of workers laid off during the past month. The category can be converted to a layoff rate by dividing by total civilian employment. The result is a new leading indicator available currently.

The new indicator's lead-lag record during the business cycle from 1969 to 1982 is shown in table 1, together with the records of the related series. The layoff series, which we have seasonally adjusted, and the unemployment claims measure performed identically at all four troughs. The new series led at all four peaks, while initial claims led at three of the four.

Compared with the total layoff rate, the new indicator has longer leads at several turns, as would be expected because the new series reflects recent actions, whereas total layoffs include many who were laid off months earlier. Relative to the manufacturing layoff rate during the overlapping period of 1969–81, the new indicator shows longer leads at three of the four peaks, and about the same timing at the troughs. The manufacturing layoff rate, in turn, has a somewhat better leading record than temporary layoffs before 1969. Therefore, it seems reasonable to join the manufacturing layoff rate before 1969 to the new rate after 1969 to form a longer series with one break in coverage. It leads at 14 of the 16 business cycle turns from 1948 to 1982, with coincident timing in the other two turns and an overall average lead time of 6 months. The combined series is a more consistent leader than initial claims for unemployment insurance, which has coincident timing four times and *lags* twice during the same period.

So far as other important indicator characteristics are concerned, such as prompt availability and freedom from extra cycles and erratic movements, the new layoff rate stands up reasonably well to its competitors. Because it is a product of the household employment survey, the figures for a previous month are normally available on the first Friday of the following month. These figures are subject to revision annually, when seasonal factors are changed. Initial claims are available weekly, with a 2-week delay, which puts them on a par with the new layoff rate, although the monthly average is not available until the middle of the following month. Erratic movements in the new layoff rate are relatively large, however, as the following measures show:[2]

	Ratio of irregular to cyclical change	*Months for cyclical dominance*
New layoff rate, under 5 weeks, 1969–85	2.51	3
Manufacturing layoff rate, 1948–75	2.08	3
Initial claims, unemployment insurance, 1948–82	2.00	3

In all three series, it takes a span of 3 months for the average cyclical change to exceed the average irregular change.

The layoff rate and initial claims series tend to lead at business cycle peaks by much longer intervals than at

troughs. In this respect, they are similar to the total unemployment rate, which leads at peaks but usually lags at troughs. The primary reason for this asymmetry is that business cycle dates are based upon data that reflect the long-run growth of the economy, whereas layoff and unemployment rates are relatively "trendless." A trendless series tends to reach earlier peaks and later troughs than a series with a rising trend. When the turns in the layoff rates are matched with those in the total unemployment rate, rather than the business cycle, the leads are more nearly symmetrical. (See table 2.) The new layoff rate series leads the downturns in unemployment by an average of 5 months and the upturns by 7 months, for an overall average lead of 6 months.

Compared with employment, the new layoff rate again leads at both peaks and troughs, but by much longer intervals at peaks. This is to be expected, because nonfarm employment is virtually coincident with the business cycle, and reflects the growth trend of the economy.

In view of the record of the new layoff rate as a leading indicator, the Center for International Business Cycle Research has revised its leading employment index to include the new layoff rate since 1969 and the manufacturing layoff rate prior to 1969. At some future date, the new indicator might be considered a candidate for the Bureau of Economic Analysis' composite leading index, replacing initial claims for unemployment insurance. □

Union response to changes in printing technology: another view

David J. Eisen

In the July 1985 issue of the *Review*, Michael Wallace presents a three-nation comparison of union response to the massive technological changes in the newspaper printing industry over the last two decades.[1] Professor Wallace contends that the historical craft orientation of U.S. printing unions and the resulting fragmentation of the labor movement in the industry have seriously impaired workers' ability to deal on an equal footing with management concerning the changes. He asserts, moreover, that a belated wave of mergers between the unions over the last 10 years has done little to give labor the appearance of a united front on the technology issue, citing in particular what he describes as a continuing jurisdictional struggle between The Newspaper Guild (reporters and other nonmechanical workers) and the International Typographical Union (typesetters) over the computerized setting of type. He concludes by describing labor relations patterns in the British and West German newspaper industries where, he claims, more farsighted unions took the decision at much earlier stages to consolidate or cooperate, and thus maintain their traditional control over the allocation of work.

The Newspaper Guild takes issue with Wallace on issues of both fact and interpretation:

Composition of the Guild. Wallace states that The Newspaper Guild is composed of "reporters, editors, and a few other white-collar workers." As a matter of fact, close to half the Guild's members are "other white-collar workers." The union has included advertising, circulation, business office, and other noneditorial employees since 1937 and actively seeks to represent them. On the other hand, Britain's National Union of Journalists (NUJ), which Wallace says "more than its U.S. counterpart, the Guild, seeks a broad-based membership of all white-collar workers in the industry," is, in fact, entirely limited to reporters and editors. Of course, in view of Wallace's mistaken conception of the Guild, his further statement that each of the three U.S. newspaper unions, including the Guild, "continues to be organized along occupational lines," is also incorrect. The Guild is an industrial union, and the Graphic Communications International Union (GCIU) is approaching that status.

Merger efforts. With regard to merger activity, Wallace states that the International Typographical Union (ITU) "was twice unsuccessful in completing merger negotiations with the Guild." Aside from the fact that there was only one such attempt, extending over several years, the statement seems to suggest that the Guild was the unwilling party. As a matter of fact, the Guild sought energetically to bring about a merger and had approved it by convention in June 1983; the plan fell apart when the ITU Convention unexpectedly refused to do likewise 2 months later.

There are other, less consequential errors in Wallace's discussion of merger efforts: the incumbent president, Joe Bingel, was "voted down" in the ITU's 1983 election but the Teamsters merger proposal was not on the ballot, except inferentially. And it was not the National Labor Relations Board but the Labor Department that stepped in to void the election; the NLRB has no such authority.

Guild-ITU conflict. More disturbing is Wallace's notion that "differences among journalists and composing room

---

David J. Eisen is Director of Research and Information, The Newspaper Guild.

workers over jurisdiction of cold-type technology remain a point of friction between the Guild and the ITU." There have been such differences in a few shops, where the issue has gone to arbitration, but they have not had any effect on relations between the two unions on the international level and played no role whatsoever in the breakdown of merger efforts.

This questionable evaluation carries over into Wallace's analysis of the impetus for merger negotiations. He states: "The printing unions, particularly the ITU, were slow to react to the changes wrought by the new technology and, as a result, turned to mergers out of desperation after questions of jurisdiction over the new technology had already been decided by publishers on a plant-by-plant basis." As a matter of fact, the ITU for many years made extraordinary efforts to prepare its members for new technology, setting up a training center at its headquarters to school members in the new equipment. These efforts broke down only when computerization set the stage for the complete elimination of typesetting and thus the printers' jobs. Local exceptions aside, the Typographical Union recognized that assertion of jurisdiction over work that now originated almost entirely in the newsroom was not a viable position and that the only practicable choice was a rearguard action to preserve the maximum number of jobs while obtaining the best possible compensation for printers displaced by the new equipment. The ITU's turn to merger was to a great extent motivated by the resulting swath this cut through its membership, to be sure, but it was not the primary force fueling the merger engine. That force was—and is—the compelling need for unity felt by all three unions in the face of the vastly strengthened bargaining position the new technology has given the publishers.

The case of Great Britain. Wallace's analysis also is poorly founded when it moves to Britain. He states:

> The NGA (National Graphical Association) and the NUJ (National Union of Journalists) have established joint committees dealing with technology issues. In general, the journalists have supported the NGA's contention that composing room workers should maintain jurisdiction over direct input of newspaper material into video display terminals (VDT's).

And later:

> Essentially, composing room workers have retained the right to control input of all materials into VDT's, which is critical in the leverage they have with publishers . . . . In contrast to their U.S. counterparts, the British trade unions have displayed considerable farsightedness in anticipating the impact of technological changes in their industry and responding accordingly.

This is an inaccurate picture. The British unions succeeded in fending off the impact of new technology for so long because of their strength. Now, however, the publishers are insisting, like *their* U.S. counterparts, on "capturing the original keystroke," and the jurisdictional question has arisen explosively between the two unions. The Journalists Union by no means concedes that the NGA should retain jurisdiction over input under these circumstances, because it would put the Graphical Association in the newsroom. The issue has been posed sharply in at least one shop, and the ultimate outcome is still unclear. One can hope that the two unions will avert a head-on clash and that the NGA will be able to protect its members' interests without invading the NUJ's territory. But already the NGA and the NUJ are more sharply at odds over management plans for the new technology than the Guild and the Typographers ever were. Wallace has written an epilogue to a story that has yet to unfold.

Postscript: The foregoing comments were written in October 1985. In early February of this year, publisher Rupert Murdoch moved his British newspaper operations to a new, high-technology plant outside of London, and indicated that he would no longer bargain with the Graphical Association. Unfortunately, most of Murdoch's journalists are crossing the NGA's picket lines, despite a directive by the Journalists Union to respect them. The significance of these developments for the argument speaks for itself. □

Technical Note

Computer-aided telephone interviewing used in the Hours at Work Survey

GUY A. TOSCANO

The Hours at Work Survey, a new component of U.S. productivity measures, represents the first use of Computer Assisted Telephone Interviewing (CATI) at the Bureau of Labor Statistics.[1] CATI refers to the use of interactive computer systems by interviewers during telephone contacts with survey respondents.[2] This relatively new process is in contrast to the traditional "batch" survey procedure, in which interviewing, data entry, data verification, and error correction constitute separate functions. This report describes the CATI process and presents the results of using the technique in the Hours at Work Survey.

An overview of the system

The Hours at Work CATI is an interactive system in which multiple users can access a mainframe computer data base using IBM 3270 terminals. CATI software is written in MANTIS, an application development system produced by CINCOM. Inc., and files are managed using VSAM (Virtual Storage Access Method), an IBM file management system. Communication with the data base is controlled by CICS (Customer Information Control System), also an IBM software package.

When a user logs onto the system and is properly identified, CATI displays a menu screen which contains six functions. By keying in the appropriate code, the user may select one of the following functions:

Function 1. Used to interview the survey respondent or to reconcile data failing edit criteria.

Function 2. Used to display the names of all respondents within the same primary company.

Function 3. Used to display previous year's data for a recurring respondent.

Function 4. Used to scan the data base for reports that have failed edit criteria.

Function 5. Used to scan the data base by interviewer identification code or by the date scheduled for contacting particular respondents.

Function 6. Used to print paper copies of status reports.

The following are the major features of the CATI system:

- *Form script.* A facsimile of the report form is displayed on the screen for the interviewer, along with reported data and notations on edit failures.
- *Cursor control.* The interviewer has complete cursor control and can move the cursor to any field on the facsimile report form to enter or change data.
- *Full screen editing.* While still on the telephone with a respondent, the interviewer can enter data into the mainframe data base and be immediately informed of entries that fail the system's edit criteria.

After telephone contact is established with a respondent, the interviewer simply follows the edit prompts displayed by the CATI system. If the interviewer is unable to resolve an edit failure during the initial contact, CATI provides for entry of a date on which the respondent should be recontacted for clarification. This information is stored in the data base and the file can be searched later based on the scheduled contact date. If the respondent provides an explanation or a correction, the interviewer moves the cursor to the entry in question, and keys a correction or enters an explanation code beside the entry. The system instantaneously edits the record based on the new entry and displays appropriate messages if further clarification is necessary.

With CATI, the interviewer no longer uses a pencil, paper error listing, calculator, and correction form. The edit-reconciliation process is reduced to one task—namely, using a terminal and telephone to interact with a data base containing reported data.

The phasing-in of CATI

The first Hours at Work Survey was conducted in 1982 in order to collect data for the 1981 reference year. The survey collects quarterly and annual data for hours paid (including vacations, holidays, and so forth) and hours actually spent

---

Guy A. Toscano is an economist in the Office of Survey Processing, Bureau of Labor Statistics. The Hours at Work Survey CATI system was developed by Kevin C. Tidemann, a computer systems analyst in the same office.

at work for production or nonsupervisory employees at business establishments in all nonagricultural sectors of the economy. The survey is based on a probability design to produce ratios of "hours at work" to "hours paid" for each 2-digit Standard Industrial Classification in manufacturing and 1-digit Standard Industrial Classification in nonmanufacturing. The ratios are then used in computing productivity measures for the major economic sectors.

The first annual survey was conducted entirely by mail. It was not until 1983, the second survey year, that CATI was used. Because it was not known how CATI would affect the survey response, the new system was implemented in stages over a period of several years.

1982: basic operations. The first-year operation consisted of an initial mailing of 1-page questionnaires to approximately 4,200 sample units in March, with two mail follow-ups to nonrespondents between April and June. Upon receipt, the completed reports were checked in and batched for key entry. The reported data were machine edited for validity, and data failing the edit criteria were printed on error listings for review. A report failing the edit was first checked for key entry errors, and then the respondent was contacted by mail or telephone to verify any remaining questionable entries. The resulting corrections were manually transcribed to yet another form which was sent to key entry for processing. Once again, data records with corrections would either pass or fail computer editing. If a record failed, it would go through the verification procedures again. This reiterative process continued until all data passed the prescribed edit criteria.

The data processing was labor-intensive and time-consuming. Approximately one-third of the respondents (1,200 sample units) had to be contacted for data verification. Many of these were contacted by telephone. This led the Bureau to conclude that telephone contact to clarify information previously supplied by mail was feasible and cost-effective. Although 76 percent of the initial sample units returned the survey form, the response rate—the proportion of sample units providing usable data—was only 50.4 percent.[3] The difference between the two rates occurred primarily because some reported data did not meet the survey definition of "hours at work," rendering the report unusable. A response is considered usable when a reporting unit provides acceptable data for at least one quarter of the reference year.

1983: the second year. In 1983, the survey operation was modified to incorporate CATI into the edit-reconciliation function. The questionnaires were mailed to the sample units, returned reports were batched, and data were keyed and computer edited as in the previous year. Additionally, the name and telephone number of the respondent were entered into the data base. Using the edit-reconciliation function, interviewers searched the data base for records with error codes. No paper error listings were produced, however. Instead, data failing one or more edits were displayed on a terminal video screen. The respondent was then contacted by telephone and requested to verify the reported information.

Table 1. Response rates for the BLS Hours at Work Survey over the CATI phase-in period, 1982–85

Item	1982[1]	1983[2]	1984[3]	1985[4]
Total response rate (percent)	50.4	80.1	78.2	85.2
Initial mailing	24.0	40.1	35.0	32.0
First follow-up (mail)	15.0	23.0	21.0	23.6
Second follow-up:				
Mail	11.4	17.0	13.2	12.5
CATI	—	—	9.0	17.1
Designated sample	4,170	4,584	4,582	4,565
Eligible sample	3,773	4,242	4,095	4,054

[1] No use of CATI.
[2] CATI used for edit-reconciliation only.
[3] CATI used for edit-reconciliation and follow-up of nonresponse.
[4] Augmented CATI.

CATI produced excellent results. A completion rate (sample units reporting data) of 90 percent yielded a total response rate of 80.1 percent, despite a 75-percent staff turnover from the previous year. Staff productivity was clearly enhanced through use of the new system. Although the improvement in the response rate was not entirely attributable to the implementation of CATI, it was apparent that the system enabled the staff to be more efficient in the edit-reconciliation process.

1984: initial solicitation of nonrespondents. In the third year, a prompting feature was added to CATI for use in conducting initial solicitation. The prompts display questions designed to guide the interviewer through the process of initiating solicitation by telephone. However, it was decided to use this new feature only after all efforts to obtain the data by mail had failed. This decision was based on the following considerations:

- While data being requested are generally available from the payroll records of employers, the respondent probably would not be able to provide the information by telephone without some type of prenotification. Mail solicitation gives the respondent more time to research and prepare these data.
- Before the Bureau could initiate a contact by telephone, time and resources would be needed to obtain the name and telephone number of the appropriate person to contact within each sample unit. Telephone numbers for sample units were accessible, but reaching an individual in the establishment who could provide the information was more difficult and time consuming.

After efforts to obtain data by mail ended, the CATI solicitation function was used to conduct follow-ups of the 1,079 nonrespondents. The sample units were equally and randomly assigned to each of five interviewers, who were given 10 workdays to complete the contacts and to obtain data using the CATI system.

Completion rates, measured as usable responses divided by eligible assigned units,[4] varied by interviewer from a low of 21.5 percent to a high of 78.6 percent. The interviewer with the highest completion rate had a rate that was 24.7 percent higher than the second most successful interviewer, who had a rate of 53.9 percent. The average completion rate for all interviewers using CATI was 34 percent.

Both clerical employees and junior level professionals were used in the CATI data collection procedure. All interviewers received training on the IBM 3270 terminal. In addition, recommended interviewing techniques were demonstrated using mock interviews. Although there was a standard script for introducing oneself to the respondent, interviewers were given approval to develop their own introductory statements using established guidelines.

A thorough review of the CATI solicitation procedures used by each interviewer was conducted in order to identify any cause for the large differences in the completion rates. The review revealed that certain personal characteristics of the interviewers, such as a professional demeanor and a good grasp of the subject matter, contributed significantly to effectiveness on the telephone. The results of the review were documented and used in staff selection and in training interviewers.

Collecting "hard data" by telephone generally required several telephone calls to a sample unit: first, to establish a contact who could provide the data or schedule a date when the data would be available, and later, to actually collect the data. The final survey results were comparable to those in the previous year. The response rate was 78.2 percent, of which 9 percent was obtained using CATI solicitation.

1985: monitoring continues. As in previous years, the initial survey contact was done by mail. A certified follow-up mailing was used to contact the nonrespondents. The signature on the certified return receipt was entered into the CATI data base and used to establish an initial contact person within the nonresponding unit. For program analysis, CATI was modified to keep a record of each call, including the duration of the call.

The initial response rate by mail was 32 percent. The response rates for two mail follow-ups were 23.6 percent and 12.5 percent. After mail solicitation ended, there were 1,413 sample units with eligibility not determined, of which 1,120 were contacted using the CATI system. Data were collected from two-thirds of the eligible sample units.

An average of 2.1 telephone calls was made to each sample unit, and the average time spent on each telephone contact was 5.9 minutes. CATI solicitation contributed 17.1 percent to the total response rate, which was 85.2 percent for the year.

Summary on using CATI

The BLS experience with using CATI to improve survey response has been positive. We started the first year with a response rate of 50.4 percent, and three surveys later, attained a response rate of 85.2 percent. This improvement was not wholly attributable to CATI but, rather to a combination of CATI and a more experienced staff. Even so, evidence of the benefits of CATI has been so persuasive that plans have been developed for modifying the Hours at Work Survey CATI to run on a microcomputer. Switching the system from a mainframe computer to a microcomputer will significantly reduce system operating costs and improve online computer response time. The use of CATI is also being tested for other BLS survey programs, in hopes of similarly cutting data collection time and operating costs, boosting response rates, and improving data quality. ☐

[3] Response rate = Number of units providing usable reports/(Number of eligible sample units + Number of sample units with eligibility not determined).

[4] A sample unit is deemed "ineligible" if, by the nature of its activity, it does not meet the definitions established for the Hours at Work Survey or the unit is out of business and no longer exists.

Research Summaries

Work-related deaths in 1984: BLS survey findings

DIANE M. COTTER

The number of occupational fatalities in private sector establishments with 11 employees or more was 3,740 in 1984, according to the Bureau of Labor Statistics' Annual Survey of Occupational Injuries and Illnesses. (See table 1.) The corresponding fatality rate was 6.4 per 100,000 full-time workers. About 3,300 of all deaths were related to injuries.

Among industry divisions, fatality rates ranged from 41.4 per 100,000 full-time workers in mining to 1.9 in finance, insurance, and real estate. (See table 2.) A high of 800 lives were lost in manufacturing and a low of 80, in finance, insurance, and real estate.

The fatality data are based on reports received from a sample of employers selected randomly. Participating employers provided a brief description of the object or event most directly responsible for the death. Although the sample for this survey is large (280,000 units), reported fatalities (3,740) are relatively rare events which make it tenuous to compare year-to-year changes precisely. The fatalities are classified into broad causal categories, and estimates of the percentages of fatalities are based on the total number of reported cases for the 1983 and 1984 surveys.

Analysis by cause and industry

The majority of deaths from occupational accidents in the private sector were grouped into four causal categories: highway vehicles, industrial vehicles or equipment, falls, and electrocutions. (See table 3.) Cars and trucks were involved in more than one-fourth of the work-related deaths; heart attacks caused about one-eighth; and industrial vehicles or equipment, falls, and electrocutions each contributed roughly one-tenth. The remaining deaths were related to assaults, entrapments, explosions, aircraft crashes, gas inhalation, plant machinery operations, fires, objects other than vehicles or equipment, and other causes.

Highway vehicles were the leading cause of death in 6 of the 8 industry divisions. Cars and trucks were responsible for the largest percentage of fatalities in the industries of agriculture, forestry, and fishing; manufacturing; transportation and public utilities; wholesale and retail trade; finance, insurance, and real estate; and services. About 30 percent of these over-the-road fatalities occurred in the transportation and public utilities industry, which had only 7 percent of total employment. (See table 4.) Some of these deaths were the result of employees being run over at the worksite, overturning vehicles, and collisions.

Industrial vehicles or equipment, such as tractors and high-lift trucks, were involved in nearly 11 percent of all fatalities. The construction and manufacturing industries each accounted for about one-fourth of these fatalities. These industries accounted for about 5 and 28 percent of total employment.

Approximately 11 percent of all fatalities involved falls, particularly from higher levels. More than 2 of every 5 of these deaths occurred in construction industries.

Electrocutions were the cause of roughly 10 percent of all fatalities. Almost three-tenths occurred in construction industries, and nearly one-fourth were in manufacturing industries. Some electrocutions resulted from workers receiv-

Table 1. Number and rate of fatalities for employers with 11 employees or more, private sector, 1974 through 1984

Year	Annual average employment[1] (thousands)	Number of fatalities	Incidence rate per 100,000 workers[2]
1974	54,272	4,970	9.8
1975	52,693	4,570	9.4
1976	53,693	3,940	7.9
1977	56,333	4,760	9.1
1978	59,297	4,590	8.2
1979	61,660	4,950	8.6
1980	61,677	4,400	7.7
1981	62,895	4,370	7.6
1982	61,646	4,090	7.4
1983	63,981	3,100	5.6
1984	68,006	3,740	6.4

[1] Employment is expressed as an annual average and is derived primarily from the BLS-State Current Employment Statistics program. Employment estimates have been adjusted based on data provided by the Annual Survey of Occupational Injuries and Illnesses to exclude establishments with fewer than 11 employees.

[2] The incidence rates represent the number of fatalities per 100,000 full-time workers and were calculated as: (N/EH) × 200,000,000, where:

N = number of fatalities
EH = total hours worked by all employees during calendar year
200,000,000 = base for 100,000 full-time equivalent workers (working 40 hours per week, 50 weeks per year).

Diane M. Cotter is an economist in the Office of Occupational Safety and Health Statistics, Bureau of Labor Statistics.

ing a severe shock after coming in contact with electrical wires.

Agriculture, forestry, and fishing. Highway vehicles accounted for the plurality of the fatalities, followed by industrial vehicles or equipment, and then heart attacks.

Mining—oil and gas extraction only.[1] Accidents involving industrial vehicles or equipment, highway vehicles, and falling objects—other than vehicles or equipment—were the primary causes of death.

Construction. Deaths which occurred as the result of an employee falling were the most common, followed by accidents involving highway vehicles, and industrial vehicles or equipment.

Manufacturing. Highway vehicles were the primary cause of deatn; industrial vehicles or equipment, heart attacks, and electrocutions were also leading causes.

Transportation and public utilities. Highway vehicles were the main cause of death; heart attacks and industrial vehicles or equipment were also important causes.

Wholesale and retail trade. Primary causes of death involved highway vehicles, industrial vehicles or equipment, and assaults.

Finance, insurance, and real estate. Highway vehicles caused the majority of the fatalities, and heart attacks accounted for another large portion.

Services. Highway vehicles were the major cause of death; heart attacks and electrocutions were other chief causes.

Table 2. Number and rate of occupational fatalities for employers with 11 employees or more, by industry division, 1983–1984

Industry division	1983		1984	
	Fatalities	Incidence rate[1]	Fatalities	Incidence rate[1]
Private sector	3,100	5.6	3,740	6.4
Agriculture, forestry, and fishing	80	12.7	110	16.3
Mining	240	27.6	370	41.4
Construction	670	26.3	660	22.8
Manufacturing	730	4.3	800	4.4
Transportation and public utilities	570	13.3	770	16.9
Wholesale and retail trade	440	3.3	440	3.1
Finance, insurance, and real estate	70	1.7	80	1.9
Services	310	2.2	510	3.9

[1] The incidence rates represent the number of fatalities per 100,000 full-time workers and were calculated as: (N/EH) × 200,000,000, where:

N = number of fatalities
EH = total hours worked by all employees during calendar year
2,000,000,000 = base for 100,000 full-time equivalent workers (working 40 hours per week, 50 weeks per year).

NOTE: Because of rounding, components may not add to totals.

Background of the survey

The 1984 Annual Survey of Occupational Injuries and Illnesses, authorized by the Occupational Safety and Health Act, surveyed all employers except the self-employed, farmers with fewer than 11 employees, private households, Federal, State, and local government agencies, employers with fewer than 11 employees in low-risk industries, and those establishments in which working conditions are covered by other Federal safety and health laws.

Since 1977, the published data on occupational fatalities reflect only those deaths in establishments with 11 employees or more. The 1983 report on the survey of occupational fatalities entitled, "Work-related deaths dropped sharply during 1983, BLS survey finds," was published in the

Table 3. Distribution of fatalities by cause for employers with 11 employees or more, private sector, 1983 and 1984[1]

[In percent]

Cause[2]	Total private sector[3]	Agriculture, forestry, and fishing	Mining—oil and gas extraction only	Construction	Manufacturing	Transportation and public utilities[4]	Wholesale and retail trade	Finance, insurance, and real estate	Services

Monthly Labor Review, September 1985, pp. 41–44.

The 1984 survey was comprised of a sample of 280,000 units. The relative standard errors, which are a measure of the sampling error in the estimates, are given in the following tabulation in percent and are to be used only in conjunction with the numbers of fatalities or the incidence rate for 1984 shown in tables 1 and 2:

Industry	*Relative standard error*
Private sector	8
Agriculture, forestry, and fishing	26
Mining	13
Construction	12
Manufacturing	6
Transportation and public utilities	13
Wholesale and retail trade	58
Finance, insurance, and real estate	39
Services	21

——*FOOTNOTE*——

[1] The Mine Safety and Health Administration of the U.S. Department of Labor and the Federal Railroad Administration of the U.S. Department of Transportation provided data for the number of deaths in coal, metal, and nonmetal mining and railroads but not for the objects or events involved in the cases.

Union membership of employed wage and salary workers, 1985

The number of employed wage and salary workers who were members of unions or employee associations declined from 20.1 to 17.0 million between 1980 and 1985. During the same period, the number of employed wage and salary workers rose from 87.5 to 94.5 million. Thus, the proportion of workers who were union members fell from 23.0 to 18.0 percent over the 5-year period. The number and proportion of workers represented by unions—that is, union members as well as nonmembers covered by collective bargaining agreements—also declined, from 22.5 to 19.4 million or from 25.7 to 20.5 percent of employed wage and salary workers.

Data on union employment were obtained from the Current Population Survey (CPS), conducted by the Bureau of the Census for the Bureau of Labor Statistics. The CPS collected data on workers identified by their membership in unions or by their representation at work by a union, whether or not they were members. It should be noted that the CPS union membership data covered only employed wage and salary workers, not union members who were self-employed, unemployed, retired, laid off, or who, for other reasons, were not wage and salary employees.

Industry. Among the major industry groups, the transportation, communications, and public utilities industry had the highest union membership proportion—37 percent, or 2.1 million members out of 5.7 million workers. Three other major industry groups had union membership proportions greater than the national average of 18.0 percent: the public sector—Federal, State, and local government (35.8 percent); manufacturing (24.8 percent); and construction (22.3 percent). In mining, 17.3 percent of the workers were union members, just below the national average. Among the other industry groups (wholesale and retail trade; services; and finance, insurance, and real estate), union membership rates were no higher than 7.2 percent. (See table 1.)

Union membership was disproportionately concentrated in three major industry groups. The public sector accounted for 33.8 percent of all employed union members; manufac-

Table 1. Employed wage and salary workers affiliated with a union, by selected characteristics, 1985 annual average

[Numbers in thousands]

Characteristic	Total employed	Members of unions[1]		Represented by unions[2]	
		Total	Percent of employed	Total	Percent of employed

Government workers	16,050	5,740	35.8	6,917	43.1

[1] Members of a labor union or an employee association similar to a union.

[2] Members of a labor union or an employee association similar to a union, as well as workers who report no union affiliation but whose jobs are covered by a union or employee association contract.

[3] Detail for the race groups will not add to total because separate data are not presented for "other races" and Hispanic groups.

[4] The distinction between full- and part-time workers is based on hours usually worked.

NOTE: Data refer to the sole or principal job of full- and part-time workers. Excluded are self-employed workers whose businesses are incorporated, although they technically qualify as wage and salary workers.

turing for 29.4 percent; and transportation, communications, and public utilities for 12.5 percent. Although these three groups accounted for three-fourths of union membership, they employed only 44 percent of the Nation's wage and salary workers.

Occupation. The two most heavily unionized major occupational groups were operators, fabricators, and laborers, with 31.8 percent membership, and precision production, craft, and repair workers, with 28.5 percent membership. Although membership rates were less than 16 percent among the other occupational groups, two subgroups had comparatively high rates of unionization.

About three-tenths of all union members were in the operators, fabricators, and laborers occupational group. Almost 60 percent were about equally distributed among three other major occupational groups: managerial and professional specialty; precision production, craft, and repair; and technical, sales, and administrative. The service occupations accounted for about one-tenth of the workers who were union members.

Demographic characteristics. While a larger proportion of male workers than of female workers belonged to unions (22.1 versus 13.2 percent), the pattern of change in union membership proportions across age brackets was similar for both sexes. The proportion of workers belonging to unions was smallest for workers age 16 to 24 for both men and women. (See table 1.) As workers' age rose, so did the percentage of those who belonged to unions. The highest unionization rate reported was for workers in the 45- to 64-year old bracket. This relationship held for both men and women.

A higher proportion of black than of white employees

Table 2. Median weekly earnings of full-time wage and salary workers affiliated with a union, by selected characteristics, 1985 annual average

Characteristic	Total	Represented by a union[1]	Not represented by a union

[1] Members of a labor union or an employee association similar to a union, as well as workers who report no union affiliation but whose jobs are covered by a union or an employee association contract.

[2] Detail for the race groups will not add to total because data for "other races" and Hispanic groups are not presented.

[3] Data not shown where base is less than 50,000.

NOTE: Data refer to the sole or principal job of full- and part-time workers. Excluded are self-employed workers whose businesses are incorporated although they technically qualify as wage and salary workers. Data on median weekly earnings are derived using $50 centered intervals, rather than the $10 intervals previously used.

belonged to unions, 24.3 and 17.3 percent. This relationship held for both men and women.

Earnings. Full-time unionized workers had substantially higher median usual weekly earnings than those who were not represented by a union. (See table 2.) This relationship held for six of the eight major industry groups (exceptions were mining and finance, insurance, and real estate) and among the occupational groups, except for managerial and professional specialty workers. Similarly, among black and white workers of both sexes, those covered by a collective bargaining agreement had weekly earnings substantially higher than their nonrepresented counterparts.

More detailed data appear in Larry T. Adams, "Union Membership of Employed Wage and Salary Workers," *Current Wage Developments*, March 1985, pp. 45-50. ☐

Making work more human

Where work is badly organized, the morale of the workers is almost certainly going to be low, and the working atmosphere depressed. Monotonous jobs, requiring little skill, can be extremely tiring and even degrading. An authoritarian style of management can add to the burden. If a worker has only one duty and that is to be obedient; if he is given only simple tasks, to be repeated from morning till night; if the pace of work allows him no time to relax for a moment; in all these conditions, he is gradually forced into the position of a draught animal who only works, eats, and sleeps. Fortunately, it is now increasingly acknowledged that—whatever purely economic considerations might dictate—this is not good enough. Everyone is now familiar with the demand for "the humanization of work."

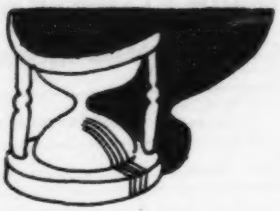
Major Agreements Expiring Next Month



This list of selected collective bargaining agreements expiring in June is based on information collected by the Bureau's Office of Wages and Industrial Relations. The list includes agreements covering 1,000 workers or more. Private industry is arranged in order of Standard Industrial Classification.

Employer and location	Industry or activity	Labor organization[1]	Number of workers
Private			
Kennecott Copper Corp. (Interstate)	Mining	Steelworkers	4,600
Magma Copper Co. (Superior, AZ)	Mining	Steelworkers	2,800
Inspiration Consolidated Copper Co. (Arizona)	Mining	Various unions	1,000
Associated General Contractors of California, Inc., and 2 others (California)	Construction	Carpenters	20,000

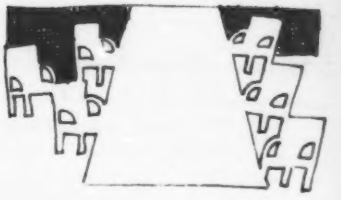
Developments in Industrial Relations



Container contracts call for two-tier pay system

A 16-day strike ended when four container manufacturers and the Steelworkers agreed on 3-year contracts for 13,300 employees. The first settlement was with National Can Corp., followed hours later by agreements on similar terms at Continental Can Co., American Can Co., and Crown Cork & Seal Co. This company-by-company bargaining was a departure from the employers' practice of bargaining as a unit, but the union was able to maintain similar terms at all of the companies.

The contracts do not provide for specified wage increases, but the workers will receive an immediate $400 lump-sum payment and $300 payments in the second and third years. They will also continue to be eligible for annual cost-of-living pay adjustments.

In a change that will save money for the companies, the union agreed to a temporary two-tier pay system under which new workers will be paid 20 percent less than the regular rate for the job during their first 2 years of employment. Leon Lynch, the union's chief negotiator for the industry, explained, "our members are some of the highest paid workers in the industrial sector, and workers who come in off the street don't always have the highest skills." At the time of the settlements, pay rates ranged from $12.55 to $15.93 an hour, according to the union.

The new contracts, which expire February 19, 1989, also provide for:

- A $3 increase in the monthly pension rate for each year of credited service.
- A health care cost containment program including preadmission reviews of non-emergency surgery, second opinion requirements, 20 percent co-payments for employees who do not follow the requirements of the program (one "learning experience" is permitted in the first year); establishment of a mail order generic drug program; and a medical expense audit program under which employees can recover up to $500.
- A voluntary product promotion program financed through payroll deductions.
- A joint committee, financed 85 percent by the company and 15 percent by the union, to determine if "special treatment" is necessary to preserve plants that continue to manufacture three-piece cans.

Volkswagen pay catches 'Big Three' automakers

Volkswagen of America and the United Auto Workers negotiated new contracts for plants in New Stanton, PA, and South Charleston, WV. The 3-year New Stanton accord, covering 2,200 employees, brought wage and benefit levels up to parity with General Motors Corp., Ford Motor Co., and Chrysler Corp. The immediate pay increase ranged from 3 cents to $1.69 an hour. For assemblers, the most heavily populated job category, the increase was 13 cents an hour, bringing the rate to $13.46. In April 1987, the employees will receive a lump-sum payment equal to 3 percent of their earnings during the preceding 12 months. Their April 1988 pay increase will match the initial increase resulting from the union's 1987 bargaining with Ford and General Motors.

Other provisions included a $6 increase in the pension calculation rate over the term, bringing the range to $18.75-$19.50 a month for each year of credited service; a 6-cent per hour increase in Volkswagen's financing of Supplemental Unemployment Benefits; and increased sickness and accident benefits.

The company also agreed to place the Auto Workers' logo on vehicles assembled at the plant, and to give the union 60 days' notice of planned subcontracting of work that will eliminate five or more jobs.

The agreement for the South Charleston stamping plant runs to June 30, 1987, the date the facility is scheduled to close if a buyer is not found. Provisions to aid the 750 employees include:

- a new income maintenance program financed by a company payment of 51.3 cents per hour—1.5 times the amount necessary to attain parity with the "Big Three" auto companies;
- a plan for converting Supplemental Unemployment Benefits to a separation pay fund, paying displaced workers amounts equivalent to 50 hours of pay for those with 2 years of service up to 570 hours for those with 13 or more years of service;
- an early retirement provision giving employees age 50 with 10 years of service lifetime benefits calculated at $12.75 to $13.50 a month for each year of service, plus supplemental benefits until age 62, calculated at $11 a month for each year of service; and

---

"Developments in Industrial Relations" is prepared by George Ruben of the Division of Developments in Labor-Management Relations, Bureau of Labor Statistics, and is largely based on information from secondary sources.

- continuation of health insurance and job search assistance for 6 months after layoff.

The South Charleston employees will receive a lump-sum payment in April 1987 equal to 2.25 percent of their earnings during the preceding 12 months. They will also receive automatic quarterly cost-of-living pay adjustments during the contract's term.

UAW to intensify organizing efforts at Honda

The United Auto Workers' plan to organize foreign-owned vehicle and parts plants opening in the United States suffered a blow when the union was forced to drop its bid for a representation election at the Honda of America Manufacturing Corp.'s plant in Marysville, OH. The union said the withdrawal of its petition to the National Labor Relations Board was a temporary action. It attributed the setback to confusion resulting from unfair labor practices charges it had filed against Honda (which were rejected by the Board), "misinformation" being spread by anti-UAW workers, and an influx of new employees. The UAW said the withdrawal of the election petition was not a defeat and that the drive to organize the Honda operations will be intensified.

In the charges filed with the Board late last year, the UAW contended that Honda had attempted to influence the election outcome by illegally questioning plant workers about their attitude toward unions, allowing anti-union material to be distributed on company time, and improving employees benefits during the organizing drive. The Board dismissed the complaint, citing "insufficient evidence."

So far, the UAW has not been successful in organizing any of the Japanese-owned automobile plants that have resisted the union's efforts. UAW does represent workers at the General Motors-Toyota joint venture in Fremont, CA, and will represent workers at the Mazda plant being built in Flat Rock, MI, and has represented workers at the Volkswagen plant in New Stanton, PA, since 1978.

Court contract allows drug testing

Drug testing and treatment provisions were adopted in a settlement between New York State's Office of Court Administration and three unions representing 3,000 court officers and clerks in State courts in New York City. Howard Rubenstein, director of employee relations for the Office of Court Administration, said the agency was committed to adopting similar provisions for the rest of the State court system when labor contracts expire in 1988.

Both the Office of Court Administration and the three unions indicated that the drug control provisions were a preventive measure rather than a reaction to an existing problem. Rubenstein said, "We think it's an issue whose time has come. These are people who carry guns, and I think we have a duty to assure the public." A union official indicated that the unions were not pleased with the program but had accepted it because the workers' sensitive duties required them to be above suspicion.

Under the provisions, the deputy chief administrative judge in the area will determine if there is "reasonable cause" to test a particular employee. If so, and the test is positive, the employee will be given the option of entering a rehabilitation program rather than facing disciplinary action. After completing the program, which will vary in scope and duration according to the employee's needs, the employee will be subject to periodic retesting and disciplinary action if drug abuse is again detected.

Other contract terms included wage increases of 5 percent retroactive to June 13, 1985, 5.5 percent on April 1, 1986, and 6 percent on April 1, 1987. The unions, comprising a joint bargaining council sponsored by the International Longshoremen's Association, are the Court Officers Association, the New York State Supreme Court Officers Association, and the Court Clerks Associations.

New rules on drug, alcohol use by rail workers

After years of controversy, the Department of Transportation issued regulations banning railroad workers from reporting to work under the influence of alcohol or drugs or consuming them on the job. The rules had been scheduled to go into effect on November 1, 1985, but were delayed by legal challenges by railroad unions. Implementation of the rules became possible when the Supreme Court favored the Government's position.

The new rules also authorize testing of employees following major accidents; when there are indications of possible impairment; and as a routine part of the hiring procedure. The regulations also require railroads to establish incentives for addicted employees to seek help voluntarily, but also permit employers to dismiss workers who violate the drug and alcohol rules.

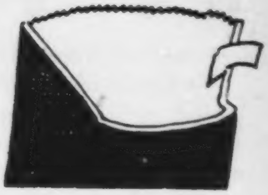
One of the first calls for adoption of the rules came from the National Transportation Safety Board in 1974. There have been 48 train accidents since 1975 attributed to employees impaired by alcohol or drugs, resulting in 37 deaths and $34 million in property damage.

Displaced airline workers given rehire rights

In the airline transportation industry, the Department of Labor issued rules providing rehiring rights for employees who lost their jobs as a result of the Airline Deregulation Act of 1978, which opened the industry to intense competition. Under the rules, all airlines must list their job vacancies on a central register and airlines that were in existence when the law took effect must give preference to applicants with rehiring rights. Preferential hiring is limited to persons who were employed by an airline for at least 4 years prior to 1978.

The hiring preference rule, authorized by the deregulation act, was originally expected to continue for 10 years, but because of delays resulting from legal challenges by the airlines, will now extend for fewer than 3 years. □

Book Reviews



A neoclassical perspective

Labor Market Economics. By Saul D. Hoffman. Englewood Cliffs, NJ, Prentice-Hall, Inc., 1986. 354 pp. $28.95.

The first interesting thing about this book appears on its cover—the title. Although the author may assume that his readership would pay no particular attention to the word "market," that is precisely the word that piques the interest of the classical economist. Has a modern text finally been written which begins with the premise that labor is, among other things, a commodity which is bought and sold? Yes, and Saul D. Hoffman is its author.

Indeed, a major strength of this book is its sound economic analysis, which is based on the understanding that labor is not magically exempt from the economic laws and pressures which operate in a market economy. (Anticipating the objections of those who would say that today's economy is too far removed from the free-market ideal to justify such an approach, Hoffman has included a convincing defense.) The use of the traditional economic tools of analysis, avoiding the need to reinvent the wheel in order to examine the subject, contributes to the effectiveness of this text, which uses a "neoclassical" perspective.

This comprehensive study is well written and well organized. There are separate chapters on demand for labor, labor supply, human capital, discrimination, unions, income, and unemployment, as well as one on "further topics." "Applications sections" are employed, many of which delve into real-world cases. Much of the author's analysis is quite enlightening, while imprecisions are mostly minimal. The exception is the statement: ". . . it should be obvious that the wage income of all workers is exactly equal to the labor costs of all firms." The author should have added a section on benefits as an aspect of compensation, or included a disclaimer stating that the term "wages" is used synonymously with "compensation." Also, because the idea of labor cost is not useful without considering productivity, it cannot be considered in such absolute terms. In a lesser violation, Puerto Rico is listed as one of the "countries" (sic) which has minimum wage legislation.

Although some equations and graphs merely quantify the obvious, most are helpful. Hoffman makes good use of new ideas and research. Divergent opinions are presented in a balanced, unbiased manner. Overall, *Labor Market Economics* is an excellent choice for the introductory college course and for those interested in the subject.

Pruning the executive branch

Servants of the People: The Uncertain Future of the Federal Civil Service. By Howard Rosen. Salt Lake City, UT, Olympus Publishing Co., 1985. 188 pp. $12.95, paper.

Howard Rosen has presented a frank, well-written book concerning the Federal Government's personnel system. This is more than just a good textbook about the personnel system, although any professor who chose this as a text would be doing students a favor. It is also a frank assessment of the follies and foibles of the system which the government has saddled itself for many years.

Rosen speaks with the authority of a man who understands the system. If there is a dimension missing from Rosen's perceptions, it stems from the fact that this book represents a personnel view of the system rather than that of a line manager. When he poses the question, "Who Manages the Workforce?" he is eloquent in explaining how the system is weak and outmoded as a management tool, but he never states clearly that it is the *managers* who are supposed to be using the tool, because they are in charge of the work force and are its most critical element. Thus, managers are let off Rosen's hook.

The author also deals inadequately with the current topic of contracting out work formerly done by civil servants. The chapter entitled, "The Contracting-Out Industry: An Extension of the Federal Labor Force?" treats the issue of government contracting on far too narrow a base, ignoring decades of broader government-industry contract relationships in major program arenas such as military weapons system manufacture, NASA's large scale R&D contracts, and extensive grant-based programs for highways, water treatment, and other public infrastructure.

Finally, Rosen seems reluctant to deal with a difficult question: what happens when, for reasonable and legitimate reasons, the Federal work force must be cut back? He suggests that cutbacks are made solely for short term and questionable reasons. But managers in the private sector and in State and local government have faced numerous situations where cutting back the work force was a correct decision and had to be done. We need to stop denying that this reality cannot and should not occur in the Federal Government. Instead, we need to deal with the necessary political and systemic changes in order to consider this possibility realistically and, where justified, handle cutbacks sensibly and humanely.

If there is a threat to the civil service system, it is, as Rosen states, that the American public will lose the recognition that this enormously talented body of employees are indeed the servants of the people. This ethic is a great strength for government. The most corrosive thing that the political leadership can do is to believe that this talent is irrelevant and unneeded in the conduct of the public's business, and that government can be run on a combination of a deeper, thicker layer of political appointees, and a mass of clerks. Rosen attempts to emphasize that this is bad judgment on the part of politicians. I suggest the American public knows better.

NOTES ON CURRENT LABOR STATISTICS

This section of the *Review* presents the principal statistical series collected and calculated by the Bureau of Labor Statistics: series on labor force, employment, unemployment, collective bargaining settlements, consumer, producer, and international prices, productivity, international comparisons, and injury and illness statistics. In the notes that follow, the data in each group of tables is briefly described, key definitions are given, notes on the data are set forth, and sources of additional information are cited.

General notes

The following notes apply to several tables in this section:

Seasonal adjustment. Certain monthly and quarterly data are adjusted to eliminate the effect on the data of such factors as climatic conditions, industry production schedules, opening and closing of schools, holiday buying periods, and vacation practices, which might prevent short-term evaluation of the statistical series. Tables containing data that have been adjusted are identified as "seasonally adjusted." (All other data are not seasonally adjusted.) Seasonal effects are estimated on the basis of past experience. When new seasonal factors are computed each year, revisions may affect seasonally adjusted data for several preceding years. (Seasonally adjusted data appear in tables 1–3, 4–10, 13, 14, and 18.) Beginning in January 1980, the BLS introduced two major modifications in the seasonal adjustment methodology for labor force data. First, the data are being seasonally adjusted with a new procedure called X–11 ARIMA, which was developed at Statistics Canada as an extension of the standard X–11 method previously used by BLS. A detailed description of the procedure appears in *The X–11 ARIMA Seasonal Adjustment Method* by Estla Bee Dagum (Statistics Canada, Catalogue No. 12–564E, January 1983). The second change is that seasonal factors are now being calculated for use during the first 6 months of the year, rather than for the entire year, and then are calculated at mid-year for the July-December period. However, revisions of historical data continue to be made only at the end of each calendar year.

Seasonally adjusted labor force data in tables 1 and 4–10 were revised in the February 1986 issue of the *Review*, to reflect experience through 1985.

Annual revisions of the seasonally adjusted payroll data shown in tables 13, 14, and 18 were made in July 1985 using the X–11 ARIMA seasonal adjustment methodology. New seasonal factors for productivity data in table 42 are usually introduced in the September issue. Seasonally adjusted indexes and percent changes from month to month and from quarter to quarter are published for numerous Consumer and Producer Price Index series. However, seasonally adjusted indexes are not published for the U.S. average All Items CPI. Only seasonally adjusted percent changes are available for this series.

Adjustments for price changes. Some data—such as the Hourly Earnings Index in table 17—are adjusted to eliminate the effect of changes in price. These adjustments are made by dividing current dollar values by the Consumer Price Index or the appropriate component of the index, then multiplying by 100. For example, given a current hourly wage rate of $3 and a current price index number of 150, where 1967 = 100, the hourly rate expressed in 1967 dollars is $2 ($3/150 × 100 = $2). The $2 (or any other resulting values) are described as "real," "constant," or "1967" dollars.

Additional information

Data that supplement the tables in this section are published by the Bureau in a variety of sources. Press releases provide the latest statistical information published by the Bureau; the major recurring releases are published according to the schedule preceding these general notes. More information about labor force, employment, and unemployment data and the household and establishment surveys underlying the data are available in *Employment and Earnings*, a monthly publication of the Bureau. More data from the household survey is published in the two-volume data book—*Labor Force Statistics Derived From the Current Population Survey*, Bulletin 2096. More data from the establishment survey appears in two data books—*Employment, Hours, and Earnings, United States*, and *Employment, Hours, and Earnings, States and Areas*, and the annual supplements to these data books. More detailed information on employee compensation and collective bargaining settlements is published in the monthly periodical, *Current Wage Developments*. More detailed data on consumer and producer prices are published in the monthly periodicals, *The CPI Detailed Report*, and *Producer Prices and Price Indexes*. Detailed data on all of the series in this section are provided in the *Handbook of Labor Statistics*, which is published biennally by the Bureau. BLS bulletins are issued covering productivity, injury and illness, and other data in this section. Finally, the *Monthly Labor Review* carries analytical articles on annual and longer term developments in labor force, employment and unemployment; employee compensation and collective bargaining; prices; productivity; international comparisons; and injury and illness data.

Symbols

p = preliminary. To increase the timeliness of some series, preliminary figures are issued based on representative but incomplete returns.
r = revised. Generally, this revision reflects the availability of later data but may also reflect other adjustments.
n.e.c. = not elsewhere classified.
n.e.s. = not elsewhere specified.

COMPARATIVE INDICATORS
(Tables 1–3)

Comparative indicators tables provide an overview and comparison of major BLS statistical series. Consequently, although many of the included series are available monthly, all measures in these comparative tables are presented quarterly and annually.

Labor market indicators include employment measures from two major surveys and information on rates of change in compensation provided by the Employment Cost Index (ECI) program. The labor force participation rate, the employment-to-population ratio, and unemployment rates for major demographic groups based on the Current Population ("household") Survey are presented, while measures of employment and average weekly hours by major industry sector are given using nonagricultural payroll data. The Employment Cost Index (compensation), by major sector and by bargaining status, is chosen from a variety of BLS compensation and wage measures because it provides a comprehensive measure of employer costs for hiring labor, not just outlays for wages, and it is not affected by employment shifts among occupations and industries.

Data on **changes in compensation, prices, and productivity** are presented in table 2. Measures of rates of change of compensation and wages from the Employment Cost Index program are provided for all civilian

nonfarm workers (excluding Federal and household workers) and for all private nonfarm workers. Measures of changes in: consumer prices for all urban consumers; producer prices by stage of processing; and the overall export and import price indexes are given. Measures of productivity (output per hour of all persons) are provided for major sectors.

Alternative measures of wage and compensation rates of change, which reflect the overall trend in labor costs, are summarized in table 3. Differences in concepts and scope, related to the specific purposes of the series, contribute to the variation in changes among the individual measures.

Notes on the data

Definitions of each series and notes on the data are contained in later sections of these notes describing each set of data. For detailed descriptions of each data series, see BLS *Handbook of Methods*, Volumes I and II, Bulletins 2134–1 and 2134–2 (Bureau of Labor Statistics, 1982 and 1984, respectively), as well as the additional bulletins, articles, and other publications noted in the separate sections of the *Review*'s "Current Labor Statistics Notes." Historical data for many series are provided in the *Handbook of Labor Statistics, Bulletin 2217* (Bureau of Labor Statistics, 1985). Users may also wish to consult *Major Programs, Bureau of Labor Statistics*, Report 718 (Bureau of Labor Statistics, 1985).

EMPLOYMENT DATA

(Tables 1; 4–21)

Household survey data

Description of the series

EMPLOYMENT DATA in this section are obtained from the Current Population Survey, a program of personal interviews conducted monthly by the Bureau of the Census for the Bureau of Labor Statistics. The sample consists of about 59,500 households selected to represent the U.S. population 16 years of age and older. Households are interviewed on a rotating basis, so that three-fourths of the sample is the same for any 2 consecutive months.

Definitions

Employed persons include (1) all civilians who worked for pay any time during the week which includes the 12th day of the month or who worked unpaid for 15 hours or more in a family-operated enterprise and (2) those who were temporarily absent from their regular jobs because of illness, vacation, industrial dispute, or similar reasons. Members of the Armed Forces stationed in the United States are also included in the employed total. A person working at more than one job is counted only in the job at which he or she worked the greatest number of hours.

Unemployed persons are those who did not work during the survey week, but were available for work except for temporary illness and had looked for jobs within the preceding 4 weeks. Persons who did not look for work because they were on layoff or waiting to start new jobs within the next 30 days are also counted among the unemployed. The **overall unemployment rate** represents the number unemployed as a percent of the labor force, including the resident Armed Forces. The **civilian unemployment rate** represents the number unemployed as a percent of the civilian labor force.

The **labor force** consists of all employed or unemployed civilians plus members of the Armed Forces stationed in the United States. Persons **not in the labor force** are those not classified as employed or unemployed; this group includes persons who are retired, those engaged in their own housework, those not working while attending school, those unable to work because of long-term illness, those discouraged from seeking work because of personal or job market factors, and those who are voluntarily idle. The **noninstitutional population** comprises all persons 16 years of age and older who are not inmates of penal or mental institutions, sanitariums, or homes for the aged, infirm, or needy, and members of the Armed Forces stationed in the United States. The **labor force participation rate** is the proportion of the noninstitutional populaton that is in the labor force. The **employment-population ratio** is total employment (including the resident Armed Forces) as a percent of the noninstitutional population.

Notes on the data

From time to time, and especially after a decennial census, adjustments are made in the Current Population Survey figures to correct for estimating errors during the preceding years. These adjustments affect the comparability of historical data. A description of these adjustments and their effect on the various data series appear in the Explanatory Notes of *Employment and Earnings*.

Data in tables 4–10 are seasonally adjusted, based on the seasonal experience through December 1984.

Additional sources of information

For detailed explanations of the data, see BLS *Handbook of Methods*, Bulletin 2134–1 (Bureau of Labor Statistics, 1982), chapter 1, and for additional data, *Handbook of Labor Statistics*, Bulletin 2217 (Bureau of Labor Statistics, 1985). A detailed description of the Current Population Survey as well as additional data are available in the monthly Bureau of Labor Statistics periodical, *Employment and Earnings*. Historical data from 1948 to 1982 are available in *Labor Force Statistics Derived from the Current Population Survey: A Databook*, Vols. I and II, Bulletin 2096 (Bureau of Labor Statistics, 1982).

A comprehensive discussion of the differences between household and establishment data on employment appears in Gloria P. Green, "Comparing employment estimates from household and payroll surveys," *Monthly Labor Review*, December 1969, pp. 9–20.

Establishment survey data

Description of the series

EMPLOYMENT, HOURS, AND EARNINGS DATA in this section are compiled from payroll records reported monthly on a voluntary basis to the Bureau of Labor Statistics and its cooperating State agencies by more than 200,000 establishments representing all industries except agriculture. In most industries, the sampling probabilities are based on the size of the establishment; most large establishments are therefore in the sample. (An establishment is not necessarily a firm; it may be a branch plant, for example, or warehouse.) Self-employed persons and others not on a regular civilian payroll are outside the scope of the survey because they are excluded from establishment records. This largely accounts for the difference in employment figures between the household and establishment surveys.

Definitions

An **establishment** is an economic unit which produces goods or services (such as a factory or store) at a single location and is engaged in one type of economic activity.

Employed persons are all persons who received pay (including holiday

and sick pay) for any part of the payroll period including the 12th of the month. Persons holding more than one job (about 5 percent of all persons in the labor force) are counted in each establishment which reports them.

Production workers in manufacturing include blue-collar worker supervisors and all nonsupervisory workers closely associated with production operations. Those workers mentioned in tables 12–16 include production workers in manufacturing and mining; construction workers in construction; and nonsupervisory workers in the following industries: transportation and public utilities; wholesale and retail trade; finance, insurance, and real estate; and services. These groups account for about four-fifths of the total employment on private nonagricultural payrolls.

Earnings are the payments production or nonsupervisory workers receive during the survey period, including premium pay for overtime or late-shift work but excluding irregular bonuses and other special payments. **Real earnings** are earnings adjusted to reflect the effects of changes in consumer prices. The deflator for this series is derived from the Consumer Price Index for Urban Wage Earner and Clerical Workers (CPI-W). The **Hourly Earnings Index** is calculated from average hourly earnings data adjusted to exclude the effects of two types of changes that are unrelated to underlying wage-rate developments: fluctuations in overtime premiums in manufacturing (the only sector for which overtime data are available) and the effects of changes and seasonal factors in the proportion of workers in high-wage and low-wage industries.

Hours represent the average weekly hours of production or nonsupervisory workers for which pay was received and are different from standard or scheduled hours. **Overtime hours** represent the portion of gross average weekly hours which were in excess of regular hours and for which overtime premiums were paid.

The Diffusion Index, introduced in the May 1983 *Review*, represents the percent of 185 nonagricultural industries in which employment was rising over the indicated period. One-half of the industries with unchanged employment are counted as rising. In line with Bureau practice, data for the 1-, 3-, and 6-month spans are seasonally adjusted, while those for the 12-month span are unadjusted. The diffusion index is useful for measuring the dispersion of economic gains or losses and is also an economic indicator.

Notes on the data

Establishment data collected by the Bureau of Labor Statistics are periodically adjusted to comprehensive counts of employment (called "benchmarks"). The latest complete adjustment was made with the release of May 1985 data, published in the July 1985 issue of the *Review*. Consequently, data published in the *Review* prior to that issue are not necessarily comparable to current data. Unadjusted data have been revised back to April 1983; seasonally adjusted data have been revised back to January 1980. These revisions were published in the *Supplement to Employment and Earnings* (Bureau of Labor Statistics, 1985). Unadjusted data from April 1984 forward, and seasonally adjusted data from January 1981 forward are subject to revision in future benchmarks.

Additional sources of information

Detailed data from the establishment survey are published monthly in the BLS periodical, *Employment and Earnings*. Earlier comparable unadjusted and seasonally adjusted data are published in *Employment, Hours, and Earnings, United States, 1909–84*, Bulletin 1312–12 (Bureau of Labor Statistics, 1985) and its annual supplement. For a detailed discussion of the methodology of the survey, see *BLS Handbook of Methods*, Bulletin 2134–1 (Bureau of Labor Statistics, 1982), chapter 2. For additional data, see *Handbook of Labor Statistics*, Bulletin 2217 (Bureau of Labor Statistics, 1985).

A comprehensive discussion of the differences between household and establishment data on employment appears in Gloria P. Green, "Comparing employment estimates from household and payroll surveys," *Monthly Labor Review*, December 1969, pp. 9–20.

Unemployment data by State

Description of the series

Data presented in this section are obtained from two major sources—the Current Population Survey (CPS) and the Local Area Unemployment Statistics (LAUS) program, which is conducted in cooperation with State employment security agencies.

Monthly estimates of the labor force, employment, and unemployment for States and sub-State areas are a key indicator of local economic conditions and form the basis for determining the eligibility of an area for benefits under Federal economic assistance programs such as the Job Training Partnership Act and the Public Works and Economic Development Act. Insofar as possible, the concepts and definitions underlying these data are those used in the national estimates obtained from the CPS.

Notes on the data

Data refer to State of residence. Monthly data for 11 States—California, Florida, Illinois, Massachusetts, Michigan, New York, New Jersey, North Carolina, Ohio, Pennsylvania, and Texas—are obtained directly from the CPS, because the size of the sample is large enough to meet BLS standards of reliability. Data for the remaining 39 States and the District of Columbia are derived using standardized procedures established by BLS. Once a year, estimates for the 11 States are revised to new population controls. For the remaining States and the District of Columbia, data are benchmarked to annual average CPS levels.

Additional sources of information

Information on the concepts, definitions, and technical procedures used to develop labor force data for States and sub-State areas as well as additional data on sub-States are provided in the monthly Bureau of Labor Statistics periodical, *Employment and Earnings*, and the annual report, *Geographic Profile of Employment and Unemployment* (Bureau of Labor Statistics). See also *BLS Handbook of Methods*, Bulletin 2134–1 (Bureau of Labor Statistics, 1982), chapter 4.

COMPENSATION AND WAGE DATA

(Tables 1–3; 22–29)

COMPENSATION AND WAGE DATA are gathered by the Bureau from business establishments, State and local governments, labor unions, collective bargaining agreements on file with the Bureau, and secondary sources.

Employment Cost Index

Description of the series

The **Employment Cost Index** (ECI) is a quarterly measure of the rate of change in compensation per hour worked and includes wages, salaries, and employer costs of employee benefits. It uses a fixed market basket of labor—similar in concept to the Consumer Price Index's fixed market basket of goods and services—to measure change over time in employer costs of employing labor. The index is not seasonally adjusted.

Statistical series on total compensation costs and on wages and salaries are available for private nonfarm workers excluding proprietors, the self-employed, and household workers. Both series are also available for State and local government workers and for the civilian nonfarm economy, which consists of private industry and State and local government workers combined. Federal workers are excluded.

The Employment Cost Index probability sample consists of about 2,200 private nonfarm establishments providing about 12,000 occupational observations and 700 State and local government establishments providing

3,500 occupational observations selected to represent total employment in each sector. On average, each reporting unit provides wage and compensation information on five well-specified occupations. Data are collected each quarter for the pay period including the 12th day of March, June, September, and December.

Fixed employment weights from the 1970 Census of Population are used each quarter to calculate the indexes for civilian, private, and State and local governments. These fixed weights, also used to derive all of the industry and occupation series indexes, ensure that changes in these indexes reflect only changes in compensation, not employment shifts among industries or occupations with different levels of wages and compensation. For the bargaining status, region, and metropolitan/nonmetropolitan area series, however, employment data by industry and occupation are not available from the census. Instead, the 1970 employment weights are reallocated within these series each quarter based on the current sample. Therefore, these indexes are not strictly comparable to those for the aggregate, industry, and occupation series.

Definitions

Total compensation costs include wages, salaries, and the employer costs for employee benefits.

Wages and salaries consist of earnings before payroll deductions, including production bonuses, incentive earnings, commissions, and cost-of-living adjustments.

Benefits include the cost to employers for paid leave, supplemental pay (including nonproduction bonuses), insurance, retirement and savings plans, and legally required benefits (such as social security, workers' compensation, and unemployment insurance).

Excluded from wages and salaries and employee benefits are such items as payment-in-kind, free room and board, and tips.

Notes on the data

The Employment Cost Index data series began in the fourth quarter of 1975, with the quarterly percent change in wages and salaries in the private nonfarm sector. Data on employer costs for employee benefits were included in 1980 to produce, when combined with the wages and salaries series, a measure of the percent change in employer costs for employee total compensation. State and local government units were added to the ECI coverage in 1981, providing a measure of total compensation change in the *civilian* nonfarm economy (excluding Federal employees). Historical indexes (June 1981 = 100) of the quarterly rates of change are presented in the May issue of the BLS monthly periodical, *Current Wage Developments*.

Additional sources of information

For a more detailed discussion of the Employment Cost Index, see Chapter 11, "The Employment Cost Index," in the *Handbook of Methods*, Bulletin 2134–1 (Bureau of Labor Statistics, 1982), chapter 11, and the following *Monthly Labor Review* articles: "Employment Cost Index: a measure of change in the 'price of labor'," July 1975; "How benefits will be incorporated into the Employment Cost Index," January 1978; "Estimation procedures for the Employment Cost Index," May 1982; and "Introducing new weights for the Employment Cost Index," June 1985.

Data on the ECI are also available in BLS quarterly press releases issued in the month following the reference months of March, June, September, and December; and from the *Handbook of Labor Statistics*, Bulletin 2217 (Bureau of Labor Statistics, 1985).

Collective bargaining settlements

Description of the series

Collective bargaining settlements data provide statistical measures of negotiated adjustments (increases, decreases, and freezes) in compensation (wages and benefits costs) and wages alone, quarterly for private industry and semiannually for State and local government. Compensation measures cover all collective bargaining situations involving 5,000 workers or more and wage measures cover all situations involving 1,000 workers or more. These data, covering private nonagricultural industries and State and local governments, are calculated using information obtained from bargaining agreements on file with the Bureau, parties to the agreements, and secondary sources, such as newspaper accounts. The data are not seasonally adjusted.

Settlement data are measured in terms of future specified adjustments: those that will occur within 12 months after contract ratification—first year—and all adjustments that will occur over the life of the contract expressed as an average annual rate. Adjustments are worker weighted. Both first-year and over-the-life measures exclude wage changes that may occur under cost-of-living clauses that are triggered by future movements in the Consumer Price Index.

Effective wage adjustments measure all adjustments occurring in the reference period, regardless of the settlement date. Included are changes from settlements reached during the period, changes deferred from contracts negotiated in earlier periods, and changes under cost-of-living adjustment clauses. Each wage change is worker weighted. The changes are prorated over all workers under agreements during the reference period yielding the average adjustment.

Definitions

Wage rate changes are calculated by dividing newly negotiated wages by the average hourly earnings, excluding overtime, at the time the agreement is reached. Compensation changes are calculated by dividing the change in the value of the newly negotiated wage and benefit package by existing average hourly compensation, which includes the cost of previously negotiated benefits, legally required social insurance programs, and average hourly earnings.

Compensation changes are calculated by placing a value on the benefit portion of the settlements at the time they are reached. The cost estimates are based on the assumption that conditions existing at the time of settlement (for example, methods of financing pensions or composition of labor force) will remain constant. The data, therefore, are measures of negotiated changes and not of total changes in employer cost.

Contract duration runs from the effective date of the agreement to the expiration date or first wage reopening date, if applicable. Average annual percent changes over the contract term take account of the compounding of successive changes.

Notes on the data

Care should be exercised in comparing the size and nature of the settlements in State and local government with those in the private sector because of differences in bargaining practices and settlement characteristics. A principal difference is the incidence of cost-of-living adjustment (COLA) clauses which cover only about 2 percent of workers under a few local government settlements, but cover 50 percent of workers under private sector settlements. Agreements without COLA's tend to provide larger specified wage increases than those with COLA's. Another difference is that State and local government bargaining frequently excludes pension benefits which are often prescribed by law. In the private sector, in contrast, pensions are typically a bargaining issue.

Additional sources of information

For a more detailed discussion on the series, see of the *BLS Handbook of Methods*, Bulletin 2134–1 (Bureau of Labor Statistics, 1982), chapter 10. Comprehensive data are published in press releases issued quarterly (in January, April, July, and October) for private industry, and semi-

annually (in February and August) for State and local government. Historical data and additional detailed tabulations for the prior calendar year appear in the April issue of the BLS monthly periodical, *Current Wage Developments*.

Work stoppages

Description of the series

Data on **work stoppages** measure the number and duration of major strikes or lockouts (involving 1,000 workers or more) occurring during the month (or year), the number of workers involved, and the amount of time lost because of stoppage.

Data are largely from newspaper accounts and cover only establishments directly involved in a stoppage. They do not measure the indirect or secondary effect of stoppages on other establishments whose employees are idle owing to material shortages or lack of service.

Definitions

Number of stoppages: The number of strikes and lockouts involving 1,000 workers or more and lasting a full shift or longer.

Workers involved: The number of workers directly involved in the stoppage.

Number of days idle: The aggregate number of work days lost by workers involved in the stoppages.

Days of idleness as a percent of estimated working time: Aggregate work days lost as a percent of the aggregate number of standard work days in the period multiplied by total employment in the period.

Notes on the data

This series is not comparable with the one terminated in 1981 that covered strikes involving six workers or more.

Additional sources of information

Data for each calendar year are reported in a BLS press release issued in the first quarter of the following year. Monthly data appear in the BLS monthly periodical, *Current Wage Developments*. Historical data appear in the BLS *Handbook of Labor Statistics*.

Other compensation data

Other BLS data on pay and benefits, not included in the Current Labor Statistics section of the *Monthly Labor Review*, appear in and consist of the following:

Industry Wage Surveys provide data for specific occupations selected to represent an industry's wage structure and the types of activities performed by its workers. The Bureau collects information on weekly work schedules, shift operations and pay differentials, paid holiday and vacation practices, and information on incidence of health, insurance, and retirement plans. Reports are issued throughout the year as the surveys are completed. Summaries of the data and special analyses also appear in the *Monthly Labor Review*.

Area Wage Surveys annually provide data for selected office, clerical, professional, technical, maintenance, toolroom, powerplant, material movement, and custodial occupations common to a wide variety of industries in the areas (labor markets) surveyed. Reports are issued throughout the year as the surveys are completed. Summaries of the data and special analyses also appear in the *Review*.

The National Survey of Professional, Administrative, Technical, and Clerical Pay provides detailed information annually on salary levels and distributions for the types of jobs mentioned in the survey's title in private employment. Although the definitions of the jobs surveyed reflect the duties and responsibilities in private industry, they are designed to match specific pay grades of Federal white-collar employees under the General Schedule pay system. Accordingly, this survey provides the legally required information for comparing the pay of salaried employees in the Federal civil service with pay in private industry. (See Federal Pay Comparability Act of 1970, 5 U.S.C. 5305.) Data are published in a BLS news release issued in the summer and in a bulletin each fall; summaries and analytical articles also appear in the *Review*.

Employee Benefits Survey provides nationwide information on the incidence and characteristics of employee benefit plans in medium and large establishments in the United States, excluding Alaska and Hawaii. Data are published in an annual BLS news release and bulletin, as well as in special articles appearing in the *Review*.

PRICE DATA
(Tables 2; 30–41)

PRICE DATA are gathered by the Bureau of Labor Statistics from retail and primary markets in the United States. Price indexes are given in relation to a base period (1967 = 100, unless otherwise noted).

Consumer Price Indexes

Description of the series

The **Consumer Price Index** (CPI) is a measure of the average change in the prices paid by urban consumers for a fixed market basket of goods and services. The CPI is calculated monthly for two population groups, one consisting only of urban households whose primary source of income is derived from the employment of wage earners and clerical workers, and the other consisting of all urban households. The wage earner index (CPI-W) is a continuation of the historic index that was introduced well over a half-century ago for use in wage negotiations. As new uses were developed for the CPI in recent years, the need for a broader and more representative index became apparent. The all urban consumer index (CPI-U) introduced in 1978 is representative of the 1972–73 buying habits of about 80 percent of the noninstitutional population of the United States at that time, compared with 40 percent represented in the CPI-W. In addition to wage earners and clerical workers, the CPI-U covers professional, managerial, and technical workers, the self-employed, short-term workers, the unemployed, retirees, and others not in the labor force.

The CPI is based on prices of food, clothing, shelter, fuel, drugs, transportation fares, doctors' and dentists' fees, and other goods and services that people buy for day-to-day living. The quantity and quality of these items are kept essentially unchanged between major revisions so that only price changes will be measured. All taxes directly associated with the purchase and use of items are included in the index.

Data collected from more than 24,000 retail establishments and 24,000 tenants in 85 urban areas across the country are used to develop the "U.S. city average." Separate estimates for 28 major urban centers are presented in table 31. The areas listed are as indicated in footnote 1 to the table. The area indexes measure only the average change in prices for each area since the base period, and do not indicate differences in the level of prices among cities.

Notes on the data

In January 1983, the Bureau changed the way in which homeownership costs are measured for the CPI-U. A rental equivalence method replaced the

asset-price approach to homeownership costs for that series. In January 1985, the same change was made in the CPI-W. The central purpose of the change was to separate shelter costs from the investment component of homeownership so that the index would reflect only the cost of shelter services provided by owner-occupied homes.

Additional sources of information

For a discussion of the general method for computing the CPI, see *BLS Handbook of Methods, Volume II, The Consumer Price Index*, Bulletin 2134–2 (Bureau of Labor Statistics, 1984). The recent change in the measurement of homeownership costs is discussed in Robert Gillingham and Walter Lane, "Changing the treatment of shelter costs for homeowners in the CPI," *Monthly Labor Review*, June 1982, pp. 9–14.

Additional detailed CPI data and regular analyses of consumer price changes are provided in the *CPI Detailed Report*, a monthly publication of the Bureau. Historical data for the overall CPI and for selected groupings may be found in the *Handbook of Labor Statistics*, Bulletin 2217 (Bureau of Labor Statistics, 1985).

Producer price indexes

Description of the series

Producer Price Indexes (PPI) measure average changes in prices received in primary markets of the United States by producers of commodities in all stages of processing. The sample used for calculating these indexes currently contains about 3,200 commodities and about 60,000 quotations per month selected to represent the movement of prices of all commodities produced in the manufacturing, agriculture, forestry, fishing, mining, gas and electricity, and public utilities sectors. The stage of processing structure of Producer Price Indexes organizes products by class of buyer and degree of fabrication (that is, finished goods, intermediate goods, and crude materials). The traditional commodity structure of PPI organizes products by similarity of end-use or material composition.

To the extent possible, prices used in calculating Producer Price Indexes apply to the first significant commercial transaction in the United States from the production or central marketing point. Price data are generally collected monthly, primarily by mail questionnaire. Most prices are obtained directly from producing companies on a voluntary and confidential basis. Prices generally are reported for the Tuesday of the week containing the 13th day of the month.

Since January 1976, price changes for the various commodities have been averaged together with implicit quantity weights representing their importance in the total net selling value of all commodities as of 1972. The detailed data are aggregated to obtain indexes for stage-of-processing groupings, commodity groupings, durability-of-product groupings, and a number of special composite groups. All Producer Price Index data are subject to revision 4 months after original publication.

Notes on the data

Beginning with the January 1986 issue, the *Review* is no longer presenting tables of Producer Price Indexes for commodity groupings, special composite groups, or SIC industries. However, these data will continue to be presented in the Bureau's monthly publication *Producer Price Indexes*. Series on the net output of major mining and manufacturing industry groups will appear in the *Review* starting with data for July 1986.

The Bureau has completed the first major stage of its comprehensive overhaul of the theory, methods, and procedures used to construct the Producer Price Indexes. Changes include the replacement of judgment sampling with probability sampling techniques; expansion to systematic coverage of the net output of virtually all industries in the mining and manufacturing sectors; a shift from a commodity to an industry orientation; the exclusion of imports from, and the inclusion of exports in, the survey universe; and the respecification of commodities priced to conform to Bureau of the Census definitions. These and other changes have been phased in gradually since 1978. The result is a system of indexes that is easier to use in conjunction with data on wages, productivity, and employment and other series that are organized in terms of the Standard Industrial Classification and the Census product class designations.

Additional sources of information

For a discussion of the methodology for computing Producer Price Indexes, see *BLS Handbook of Methods*, Bulletin 2134–1 (Bureau of Labor Statistics, 1982), chapter 7.

Additional detailed data and analyses of price changes are provided monthly in *Producer Price Indexes*. Selected historical data may be found in the *Handbook of Labor Statistics*, Bulletin 2217 (Bureau of Labor Statistics, 1985).

International price indexes

Description of the series

The BLS **International Price Program** produces quarterly export and import price indexes for nonmilitary goods traded between the United States and the rest of the world. The export price index provides a measure of price change for all products sold by U.S. residents to foreign buyers. ("Residents" is defined as in the national income accounts: it includes corporations, businesses, and individuals but does not require the organizations to be U.S. owned nor the individuals to have U.S. citizenship.) The import price index provides a measure of price change for goods purchased from other countries by U.S. residents. With publication of an all-import index in February 1983 and an all-export index in February 1984, all U.S. merchandise imports and exports now are represented in these indexes. The reference period for the indexes is 1977 = 100, unless otherwise indicated.

The product universe for both the import and export indexes includes raw materials, agricultural products, semifinished manufactures, and finished manufactures, including both capital and consumer goods. Price data for these items are collected quarterly by mail questionnaire. In nearly all cases, the data are collected directly from the exporter or importer, although in a few cases, prices are obtained from other sources.

To the extent possible, the data gathered refer to prices at the U.S. border for exports and at either the foreign border or the U.S. border for imports. For nearly all products, the prices refer to transactions completed during the first 2 weeks of the third month of each calendar quarter—March, June, September, and December. Survey respondents are asked to indicate all discounts, allowances, and rebates applicable to the reported prices, so that the price used in the calculation of the indexes is the actual price for which the product was bought or sold.

In addition to general indexes of prices for U.S. exports and imports, indexes are also published for detailed product categories of exports and imports. These categories are defined by the 4- and 5-digit level of detail of the Standard Industrial Trade Classification System (SITC). The calculation of indexes by SITC category facilitates the comparison of U.S. price trends and sector production with similar data for other countries. Detailed indexes are also computed and published on a Standard Industrial Classification (SIC-based) basis, as well as by end-use class.

Notes on the data

The export and import price indexes are weighted indexes of the Laspeyeres type. Price relatives are assigned equal importance within each weight category and are then aggregated to the SITC level. The values assigned to each weight category are based on trade value figures compiled

by the Bureau of the Census. The trade weights currently used to compute both indexes relate to 1980.

Because a price index depends on the same items being priced from period to period, it is necessary to recognize when a product's specifications or terms of transaction have been modified. For this reason, the Bureau's quarterly questionnaire requests detailed descriptions of the physical and functional characteristics of the products being priced, as well as information on the number of units bought or sold, discounts, credit terms, packaging, class of buyer or seller, and so forth. When there are changes in either the specifications or terms of transaction of a product, the dollar value of each change is deleted from the total price change to obtain the "pure" change. Once this value is determined, a linking procedure is employed which allows for the continued repricing of the item.

For the export price indexes, the preferred pricing basis is f.a.s. (free alongside ship) U.S. port of exportation. When firms report export prices f.o.b. (free on board), production point information is collected which enables the Bureau to calculate a shipment cost to the port of exportation. An attempt is made to collect two prices for imports. The first is the import price f.o.b. at the foreign port of exportation, which is consistent with the basis for valuation of imports in the national accounts. The second is the import price c.i.f. (cost, insurance, and freight) at the U.S. port of importation, which also includes the other costs associated with bringing the product to the U.S. border. It does not, however, include duty charges.

Additional sources of information

For a discussion of the general method of computing International Price Indexes, see *BLS Handbook of Methods*, Bulletin 2134–1 (Bureau of Labor Statistics, 1982), chapter 8.

Additional detailed data and analyses of international price developments are presented in the Bureau's quarterly publication *U.S. Import and Export Price Indexes* and in occasional *Monthly Labor Review* articles prepared by BLS analysts. Selected historical data may be found in the *Handbook of Labor Statistics*, Bulletin 2217 (Bureau of Labor Statistics, 1985).

PRODUCTIVITY DATA
(Tables 2; 42–44)

U. S. productivity and related data

Description of the series

The productivity measures relate real physical output to real input. As such, they encompass a family of measures which include single factor input measures, such as output per unit of labor input (output per hour) or output per unit of capital input, as well as measures of multifactor productivity (output per unit of labor and capital inputs combined). The Bureau indexes show the change in output relative to changes in the various inputs. The measures cover the business, nonfarm business, manufacturing, and nonfinancial corporate sectors.

Corresponding indexes of hourly compensation, unit labor costs, unit nonlabor payments, and prices are also provided.

Definitions

Output per hour of all persons (labor productivity) is the value of goods and services in constant prices produced per hour of labor input. **Output per unit of capital services** (capital productivity) is the value of goods and services in constant dollars produced per unit of capital services input.

Multifactor productivity is the ratio output per unit of labor and capital inputs combined. Changes in this measure reflect changes in a number of factors which affect the production process such as changes in technology, shifts in the composition of the labor force, changes in capacity utilization, research and development, skill and efforts of the work force, management, and so forth. Changes in the output per hour measures reflect the impact of these factors as well as the substitution of capital for labor.

Compensation per hour is the wages and salaries of employees plus employers' contributions for social insurance and private benefit plans, and the wages, salaries, and supplementary payments for the self-employed (except for nonfinancial corporations in which there are no self-employed)—the sum divided by hours paid for. **Real compensation per hour** is compensation per hour deflated by the change in the Consumer Price Index for All Urban Consumers.

Unit labor costs is the labor compensation costs expended in the production of a unit of output and is derived by dividing compensation by output. **Unit nonlabor payments** include profits, depreciation, interest, and indirect taxes per unit of output. They are computed by subtracting compensation of all persons from current dollar value of output and dividing by output. **Unit nonlabor costs** contain all the components of unit nonlabor payments *except* unit profits.

Unit profits include corporate profits and the value of inventory adjustments per unit of output.

Hours of all persons are the total hours paid of payroll workers, self-employed persons, and unpaid family workers.

Capital services is the flow of services from the capital stock used in production. It is developed from measures of the net stock of physical assets—equipment, structures, land, and inventories—weighted by rental prices for each type of asset.

Labor and capital inputs combined are derived by combining changes in labor and capital inputs with weights which represent each component's share of total output. The indexes for capital services and combined units of labor and capital are based on changing weights which are averages of the shares in the current and preceding year (the Tornquist index-number formula).

Notes on the data

Output measures for the business sector and the nonfarm businesss sector exclude the constant dollar value of owner-occupied housing, rest of world, households and institutions, and general government output from the constant dollar value of gross national product. The measures are derived from data supplied by the Bureau of Economic Analysis, U.S. Department of Commerce, and the Federal Reserve Board. Quarterly manufacturing output indexes are adjusted by the Bureau of Labor Statistics to annual estimates of output (gross product originating) from the Bureau of Economic Analysis. Compensation and hours data are developed from data of the Bureau of Labor Statistics and the Bureau of Economic Analysis.

The productivity and associated cost measures in tables 42–44 describe the relationship between output in real terms and the labor time and capital services involved in its production. They show the changes from period to period in the amount of goods and services produced per unit of input. Although these measures relate output to hours and capital services, they do not measure the contributions of labor, capital, or any other specific factor of production. Rather, they reflect the joint effect of many influences, including changes in technology; capital investment; level of output; utilization of capacity, energy, and materials; the organization of production; managerial skill; and the characteristics and efforts of the work force.

Additional sources of information

Descriptions of methodology underlying the measurement of output per hour and multifactor productivity are found in the *BLS Handbook of Methods*, Bulletin 2134–1 (Bureau of Labor Statistics, 1982), chapter 13. Historical data for selected industries are provided in the Bureau's *Handbook of Labor Statistics*, 1985, Bulletin 2217.

INTERNATIONAL COMPARISONS

(Tables 45–47)

Labor force and unemployment

Description of the series

Tables 45 and 46 present comparative measures of the labor force, employment, and unemployment—approximating U.S. concepts—for the United States, Canada, Australia, Japan, and six European countries. The unemployment statistics (and, to a lesser extent, employment statistics) published by other industrial countries are not, in most cases, comparable to U.S. unemployment statistics. Therefore, the Bureau adjusts the figures for selected countries, where necessary, for all known major definitional differences. Although precise comparability may not be achieved, these adjusted figures provide a better basis for international comparisons than the figures regularly published by each country.

Definitions

For the principal U.S. definitions of the **labor force**, **employment**, and **unemployment**, see the Notes section on EMPLOYMENT DATA: Household Survey Data.

Notes on the data

The adjusted statistics have been adapted to the age at which compulsory schooling ends in each country, rather than to the U.S. standard of 16 years of age and over. Therefore, the adjusted statistics relate to the population age 16 and over in France, Sweden, and from 1973 onward, Great Britain; 15 and over in Canada, Australia, Japan, Germany, the Netherlands, and prior to 1973, Great Britain; and 14 and over in Italy. The institutional population is included in the denominator of the labor force participation rates and employment-population ratios for Japan and Germany; it is excluded for the United States and the other countries.

In the U.S. labor force survey, persons on layoff who are awaiting recall to their job are classified as unemployed. European and Japanese layoff practices are quite different in nature from those in the United States; therefore, strict application of the U.S. definition has not been made on this point. For further information, see *Monthly Labor Review*, December 1981, pp. 8–11.

The figures for one or more recent years for France, Germany, Great Britain, Italy, and the Netherlands are calculated using adjustment factors based on labor force surveys for earlier years and are considered preliminary. The recent-year measures for these countries are, therefore, subject to revision whenever data from more current labor force surveys become available.

Additional sources of information

For further information, see *International Comparisons of Unemployment*, Bulletin 1979 (Bureau of Labor Statistics, 1978), Appendix B and unpublished Supplements to Appendix B available on request. The statistics are also analyzed periodically in the *Monthly Labor Review*. Additional historical data, generally beginning with 1959, are published in the *Handbook of Labor Statistics* and are available in unpublished statistical supplements to Bulletin 1979.

Manufacturing productivity and labor costs

Description of the series

Table 47 presents comparative measures of manufacturing labor productivity, hourly compensation costs, and unit labor costs for the United States, Canada, Japan, and nine European countries. These measures are limited to trend comparisons—that is, intercountry series of changes over time—rather than level comparisons because reliable international comparisons of the levels of manufacturing output are unavailable.

Definitions

Output is constant value output (value added), generally taken from the national accounts of each country. While the national accounting methods for measuring real output differ considerably among the 12 countries, the use of different procedures does not, in itself, connote lack of comparability—rather, it reflects differences among countries in the availability and reliability of underlying data series.

Hours refer to all employed persons including the self-employed in the United States and Canada; to all wage and salary employees in the other countries. The U.S. hours measure is hours paid; the hours measures for the other countries are hours worked.

Compensation (labor cost) includes all payments in cash or kind made directly to employees plus employer expenditures for legally required insurance programs and contractual and private benefit plans. In addition, for some countries, compensation is adjusted for other significant taxes on payrolls or employment (or reduced to reflect subsidies), even if they are not for the direct benefit of workers, because such taxes are regarded as labor costs. However, compensation does not include all items of labor cost. The costs of recruitment, employee training, and plant facilities and services—such as cafeterias and medical clinics—are not covered because data are not available for most countries. Self-employed workers are included in the U.S. and Canadian compensation figures by assuming that their hourly compensation is equal to the average for wage and salary employees.

Notes on the data

For most of the countries, the measures refer to total manufacturing as defined by the International Standard Industrial Classification. However, the measures for France (beginning 1959), Italy (beginning 1970), and the United Kingdom (beginning 1976), refer to manufacturing and mining less energy-related products and the figures for the Netherlands exclude petroleum refining from 1969 to 1976. For all countries, manufacturing includes the activities of government enterprises.

The figures for one or more recent years are generally based on current indicators of manufacturing output, employment, hours, and hourly compensation and are considered preliminary until the national accounts and other statistics used for the long-term measures become available.

Additional sources of information

For additional information, see the *BLS Handbook of Methods*, Bulletin 2134, Vol. 1, Chapter 16 (Bureau of Labor Statistics, 1982) and periodic *Monthly Labor Review* articles. Historical data are provided in the Bureau's *Handbook of Labor Statistics*, Bulletin 2217, 1985. The statistics are issued twice per year—in a news release (generally in May) and in a *Monthly Labor Review* article (generally in December).

OCCUPATIONAL INJURY AND ILLNESS DATA

(Table 48)

Description of the series

The Annual Survey of Occupational Injuries and Illnesses is designed to collect data on injuries and illnesses based on records which employers in the following industries maintain under the Occupational Safety and Health Act of 1970: agriculture, forestry, and fishing; oil and gas extraction; construction; manufacturing; transportation and public utilities; wholesale and retail trade; finance, insurance, and real estate; and services. Excluded from the survey are self-employed individuals, farmers with fewer than 11 employees, employers regulated by other Federal safety and health laws, and Federal, State, and local government agencies.

Because the survey is a Federal–State cooperative program and the data must meet the needs of participating State agencies, an independent sample is selected for each State. The sample is selected to represent all private industries in the States and territories. The sample size for the survey is dependent upon (1) the characteristics for which estimates are needed; (2) the industries for which estimates are desired; (3) the characteristics of the population being sampled; (4) the target reliability of the estimates; and (5) the survey design employed.

While there are many characteristics upon which the sample design could be based, the total recorded case incidence rate is used because it is one of the most important characteristics and the least variable; therefore, it requires the smallest sample size.

The survey is based on stratified random sampling with a Neyman allocation and a ratio estimator. The characteristics used to stratify the establishments are the Standard Industrial Classification (SIC) code and size of employment.

Definitions

Recordable occupational injuries and illnesses are: (1) occupational deaths, regardless of the time between injury and death, or the length of the illness; or (2) nonfatal occupational illnesses; or (3) nonfatal occupational injuries which involve one or more of the following: loss of consciousness, restriction of work or motion, transfer to another job, or medical treatment (other than first aid).

Occupational injury is any injury such as a cut, fracture, sprain, amputation, and so forth, which results from a work accident or from exposure involving a single incident in the work environment.

Occupational illness is an abnormal condition or disorder, other than one resulting from an occupational injury, caused by exposure to environmental factors associated with employment. It includes acute and chronic illnesses or disease which may be caused by inhalation, absorption, ingestion, or direct contact.

Lost workday cases are cases which involve days away from work, or days of restricted work activity, or both.

Lost workday cases involving restricted work activity are those cases which result in restricted work activity only.

Lost workdays away from work are the number of workdays (consecutive or not) on which the employee would have worked but could not because of occupational injury or illness.

Lost workdays—restricted work activity are the number of workdays (consecutive or not) on which, because of injury or illness: (1) the employee was assigned to another job on a temporary basis; or (2) the employee worked at a permanent job less than full time; or (3) the employee worked at a permanently assigned job but could not perform all duties normally connected with it.

The number of days away from work or days of restricted work activity does not include the day of injury or onset of illness or any days on which the employee would not have worked even though able to work.

Incidence rates represent the number of injuries and/or illnesses or lost workdays per 100 full-time workers.

Notes on the data

Estimates are made for industries and employment-size classes and for severity classification: fatalities, lost workday cases, and nonfatal cases without lost workdays. Lost workday cases are separated into those where the employee would have worked but could not and those in which work activity was restricted. Estimates of the number of cases and the number of days lost are made for both categories.

Most of the estimates are in the form of incidence rates, defined as the number of injuries and illnesses, or lost workdays, per 100 full-time employees. For this purpose, 200,000 employee hours represent 100 employee years (2,000 hours per employee). Only a few of the available measures are included in the *Handbook of Labor Statistics*. Full detail is presented in the annual bulletin, *Occupational Injuries and Illnesses in the United States, by Industry*.

Comparable data for individual States are available from the BLS Office of Occupational Safety and Health Statistics.

Mining and railroad data are furnished to BLS by the Mine Safety and Health Administration and the Federal Railroad Administration, respectively. Data from these organizations are included in BLS and State publications. Federal employee experience is compiled and published by the Occupational Safety and Health Administration. Data on State and local government employees are collected by about half of the States and territories; these data are not compiled nationally.

Additional sources of information

The Supplementary Data System provides detailed information describing various factors associated with work-related injuries and illnesses. These data are obtained from information reported by *employers* to State workers' compensation agencies. The Work Injury Report program examines selected types of accidents through an employee survey which focuses on the circumstances surrounding the injury. These data are not included in the *Handbook of Labor Statistics* but are available from the BLS Office of Occupational Safety and Health Statistics.

The definitions of occupational injuries and illnesses and lost workdays are from *Recordkeeping Requirements under the Occupational Safety and Health Act of 1970*. For additional data, see *Occupational Injuries and Illnesses in the United States, by Industry*, annual Bureau of Labor Statistics bulletin; BLS *Handbook of Methods*, Bulletin 2134–1 (Bureau of Labor Statistics, 1982), chapter 17; *Handbook of Labor Statistics*, Bulletin 2217 (Bureau of Labor Statistics, 1985), pp. 411–14; annual reports in the *Monthly Labor Review*; and annual U.S. Department of Labor press releases.

[1] The population figures are not seasonally adjusted.

[2] Civilian employment as a percent of the civilian noninstitutional population.

NOTE: Detail for the above race and Hispanic-origin groups will not sum to totals because data for the "other races" groups are not presented and Hispanics are included in both the white and black population groups.

6. Selected employment indicators, monthly data seasonally adjusted

[1] Cost (cents-per-hour worked) measured in the Employment Cost Index consists of wages, salaries and employer cost of employee benefits.

[2] Consist of private industry workers (excluding farm and household workers) and State and local government (excluding Federal Government) workers.

[3] Consists of legislative, judicial, administrative, and regulatory activities.

[4] Includes, for example, library, social, and health services.

23. Employment Cost Index, wages and salaries, by occupation and industry group

[1] The indexes are calculated differently from those for the occupation and industry groups. For a detailed description of the index calculation, see the *Monthly Labor Review* Technical Note, "Estimation procedures for the Employment Cost Index," May 1982.

25. Specified compensation and wage adjustments from contract settlements, and effective wage adjustments, private industry collective bargaining situations covering 1,000 workers or more (in percent)

Measure	Annual average		Quarterly average							
			1984				1985			
	1984	1985	I	II	III	IV	I	II^p	III^p	IV^p
Specified adjustments:										
Total compensation [1] adjustments, [2] settlements covering 5,000 workers or more:										
First year of contract	3.6	2.6	5.1	3.5	2.7	3.7	3.6	3.5	2.0	2.0
Annual rate over life of contract	2.8	2.7	4.7	3.2	3.1	2.0	2.7	3.4	3.0	1.4
Wage adjustments, settlements covering 1,000 workers or more:										
First year of contract	2.4	2.3	2.8	2.6	2.1	2.3	3.3	2.5	2.0	2.1
Annual rate over life of contract	2.4	2.7	3.3	2.7	2.6	1.5	3.2	2.8	3.1	1.9
Effective adjustments:										
Total effective wage adjustment [3]	3.7	3.3	.9	.9	1.2	.7	.8	.8	1.2	.5
From settlements reached in period	.8	.7	.1	.1	.2	.3	.1	.2	.2	.2
Deferred from settlements reached in earlier periods	2.0	1.8	.4	.7	.7	.2	.6	.5	.6	.2
From cost-of-living-adjustments clauses	.9	.8	.3	.2	.3	.2	.1	.1	.4	.1

---

[1] Compensation includes wages, salaries, and employers' cost of employee benefits when contract is negotiated.

[2] Adjustments are the net result of increases, decreases and no changes in compensation or wages.

[3] Because of rounding total may not equal sum of parts.

^{p} = preliminary.

26. Average specified compensation and wage adjustments, major collective bargaining settlements in private industry situations covering 1,000 workers or more during 4-quarter periods (in percent)

Measure	Average for four quarters ending–							
	1984				1985			
	I	II	III	IV	I	II^p	III^p	IV^p
Specified total compensation adjustments, settlements covering 5,000 workers or more, all industries:

[1] Data do not meet publication standards.

^{p} = preliminary.

27. Average effective wage adjustments, private industry collective bargaining situations covering 1,000 workers or more during 4-quarter periods (in percent)

Effective wage adjustment	Average for four quarters ending—						
	1984			1985			
	II	III	IV	I	II^p	III^p	IV^p
For all workers:[1]							
Total	4.3	4.2	3.7	3.6	3.5	3.5	3.3
From settlements reached in period	1.0	1.0	.8	.7	.9	.9	.7
Deferred from settlements reached in earlier period	2.2	2.1	2.0	2.2	1.9	1.8	1.8
From cost-of-living-adjustments clauses	1.1	1.2	.9	.7	.7	.8	.8
For workers receiving changes:							
Total	5.3	5.0	4.4	4.5	4.2	4.3	4.1
From settlements reached in period	3.6	3.7	3.0	2.9	2.9	2.8	3.4
Deferred from settlements reached in earlier period	4.9	4.2	4.0	4.2	3.9	3.7	3.7
From cost-of-living-adjustments clauses	4.0	3.2	2.7	2.3	2.3	2.8	2.2

[1] Because of rounding total may not equal sum of parts.

p = preliminary.

28. Specified compensation and wage adjustments from contract settlements, and effective wage adjustments, State and local government collective bargaining situations covering 1,000 workers or more (in percent)

Measure	Annual average		Second 6 months 1985^p
	1984	1985	
Specified adjustments:			
Total compensation [1] adjustments, [2] settlements covering 5,000 workers or more:			
First year of contract	5.2	4.2	3.8
Annual rate over life of contract	5.4	5.2	5.3
Wage adjustments, settlements covering 1,000 workers or more:			
First year of contract	4.8	4.6	4.4
Annual rate over life of contract	5.1	5.4	5.6
Effective adjustments:			
Total effective wage adjustment [3]	5.0	5.8	4.1
From settlements reached in period	1.9	4.1	3.2
Deferred from settlements reached in earlier periods	3.1	1.6	.9
From cost-of-living-adjustment clauses	(4)	(4)	(4)

[1] Compensation includes wages, salaries, and employers' cost of employee benefits when contract is negotiated.

[2] Adjustments are the net result of increases, decreases, and no change in compensation or wages.

[3] Because of rounding total may not equal sum of parts.

[4] Less than 0.05 percent.

p = preliminary.

29. Work stoppages involving 1,000 workers or more

Measure	Annual totals		1985										1986		
	1984	1985	Mar.	Apr.	May	June	July	Aug.	Sept.	Oct.	Nov.	Dec.	Jan.^{p}	Feb.^{p}	Mar.^{p}
Number of stoppages:															
Beginning in period	62	54	4	3	2	2	9	6	11	4	7	2	4	3	–
In effect during period	68	61	12	8	6	8	13	18	20	18	11	8	7	7	–
Workers involved:															
Beginning in period (in thousands)	376.0	323.9	15.2	6.2	6.9	15.7	52.3	15.3	69.5	74.6	25.0	8.2	7.6	24.0	–
In effect during period (in thousands)	391.0	584.1	48.2	14.1	14.8	29.5	60.2	66.8	93.9	117.3	64.6	38.1	12.0	28.4	–
Days idle:															
Number (in thousands)	8,499.0	7,079.1	698.5	229.5	203.3	454.3	500.2	869.7	931.4	1,433.0	651.2	685.4	17.0	309.5	–
Percent of estimated working time[1]	.04	.03	.03	.01	.01	.02	.02	.03	.04	.06	.03	.03	.01	.02	–

[1] Agricultural and government employees are included in the total employed and total working time; private household, forestry, and fishery employees are excluded. An explanation of the measurement of idleness as a percentage of the total time worked is found in "Total economy' measure of strike idleness," *Monthly Labor Review*, October 1968, pp. 54-56.

[1] Area is generally the Standard Metropolitan Statistical Area (SMSA), exclusive of farms. L.A.-Long Beach, Anaheim, Calif. is a combination of two SMSA's, and N.Y., N.Y.-Northeastern N.J. and Chicago, Ill.-Northwestern Ind. are the more extensive Standard Consolidated Areas. Area definitions are those established by the Office of Management and Budget in 1973, except for Denver-Boulder, Colo. which does not include Douglas County. Definitions do not include revisions made since 1973.

[2] Foods, fuels, and several other items priced every month in all areas; most other goods and services priced as indicated.

M - Every month.
1 - January, March, May, July, September, and November
2 - February, April, June, August, October, and December

[3] Regions are defined as the four Census regions.

The population size classes are aggregations of areas which have urban population as defined:

A-1 - More than 4,000,000
A-2 - 1,250,000 to 4,000,000
B - 385,000 to 1,250,000
C - 75,000 to 385,000
D - Less than 75,000

Population size class A is the aggregation of population size classes A-1 and A-2.

- Data not available.

NOTE: Local area CPI indexes are byproducts of the national CPI program. Because each local index is a small subset of the national index, it has a smaller sample size and is, therefore, subject to substantially more sampling and other measurement error than the national index. As a result, local area indexes show greater volatility than the national index, although their long-term trends are quite similar. Therefore, the Bureau of Labor Statistics strongly urges users to consider adopting the national average CPI for use in escalator clauses.

32. Annual data: Consumer Price Index all items and major groups

Series	1977	1978	1979	1980	1981	1982	1983	1984	1985

Germany	7.8	7.9	7.9	7.9	7.8	7.9	8.0	7.9	7.8
Great Britain	13.0	13.3	12.9	13.2	13.0	13.1	13.3	13.4	13.1
Italy	5.9	6.1	6.0	5.8	5.8	5.9	5.9	6.2	6.3
Sweden	3.1	2.8	3.1	3.1	3.0	3.0	2.9	2.8	2.7

[1] Quarterly rates are for the first month of the quarter.

[2] Major changes in the Italian labor force survey, introduced in 1977, resulted in a large increase in persons enumerated as unemployed. However, many persons reported that they had not actively sought work in the past 30 days, and they have been provisionally excluded for comparability with U.S. concepts. Inclusion of such persons would more than double the Italian unemployment rate shown.

- Data not available.

NOTE: Quarterly figures for France, Germany, and Great Britain are calculated by applying annual adjustment factors to current published data and therefore should be viewed as less precise indicators of unemployment under U.S. concepts than the annual figures.

46. Annual data: Employment status of the civilian working-age population, ten countries

---

[1] Total cases include fatalities.

[2] The incidence rates represent the number of injuries and illnesses or lost workdays per 100 full-time workers and were calculated as:
(N/EH) X 200,000, where:
N = number of injuries and illnesses or lost workdays.
EH = total hours worked by all employees during calendar year.
200,000 = base for 100 full-time equivalent workers (working 40 hours per week, 50 weeks per year.)

[3] Excludes farms with fewer than 11 employees since 1976.

Periodicals

CPI Detailed Report. Each issue provides a comprehensive report on price movements for the month, plus statistical tables, charts, and technical notes. $4 ($25 per year). January issue features an article on the Consumer Price Index revision.

Current Wage Developments. Each issue includes selected wage and benefit changes, work stoppages, and statistics on compensation changes. $2 ($21 per year). February issue features index to 1985 wage and benefit changes.

Employment and Earnings. Each issue covers employment and unemployment developments in the month plus regular statistical tables on national, State, and area employment, hours, and earnings. $4.50 ($31 per year). March issue features 1985 annual averages for national establishment survey data.

Occupational Outlook Quarterly. Each issue helps people planning careers, guidance counselors, manpower development specialists, and others keep informed of changing occupational opportunities. $3 ($11 per year).

Producer Price Indexes. Each issue includes a comprehensive report on price movements for the month, plus regular tables and technical notes. $4.25 ($29 per year). January issue features articles on expansion of the Producer Price Index; price indexes for the net output of major mining and manufacturing industry groups; recalculation of seasonal adjustment factors; and changes in table numbers and formats.

IN THE MAZE OF ECONOMIC AND SOCIAL STATISTICS,

do you sometimes feel like Stanley hunting for Livingstone?

If so, your search for a single source of reliable and comprehensive statistics and analysis is over. Subscribe to the MONTHLY LABOR REVIEW, the oldest government journal providing up-to-date information on economic and social statistics.

PUBLISHED CONTINUOUSLY SINCE 1915, the REVIEW provides a 40-page section of current statistics covering employment and unemployment; wages, and strike activity; worker and capital productivity; unit labor costs and output; consumer, industrial, and international prices; economic growth; and related topics. Each month, the REVIEW also contains articles and informative reports. Some recent titles are:

- Job Training Partnership Act
- Older workers in the labor market
- Japan's low unemployment
- Employee-owned firms
- The labor force in 1995
- Multifactor productivity
- Import prices for petroleum
- The employment cost index
- Work Injuries from falls
- Youth joblessness
- Men's and women's earnings
- Occupational winners and losers
- Black workers' gains
- Shortage of machinists?
- Price inflation remains low
- Employment in energy industries
- Collective bargaining
- Fatal injuries

Labor Month In Review

EMPLOYMENT BENCHMARK. With computation of data for May 1986, the Bureau of Labor Statistics completed its annual revision of employment, hours, and earnings data from the establishment survey. The revision uses employment counts for March 1985 as a benchmark. As part of the usual annual benchmarking process, the Bureau also revised seasonally adjusted series for the past 5 years, and computed new seasonal adjustment factors.

Adjustment procedure. Monthly estimates from the Current Employment Statistics Survey are based on information collected from a sample of establishments. These sample estimates are "benchmarked"—adjusted to reflect actual employment counts—on an annual basis. Benchmarks are counts of employment based primarily on mandatory unemployment insurance reports submitted by employers to State employment security agencies. The current revision affects unadjusted series from April 1984 (the month following the previous benchmark) forward. Seasonally adjusted series are revised from January 1981 forward. Selected hours and earnings estimates in the trade and services divisions are revised beginning with January 1984 data.

The current revisions. In March 1985, the benchmark count for total nonagricultural employment was 96.0 million, only 3,000 below the sample-based estimate for the same month. This small aggregate adjustment is the result of offsetting corrections to the total private and government sectors. A downward adjustment of 131,000 in total private employment, stemming primarily from manufacturing (down 104,000), was balanced by an upward revision of 128,000 in State and local government. Of the 255 3-digit Standard Industrial Classification industry groups for which the Bureau publishes employment estimates, only 35 were revised by 5 percent or more. As is generally the case, the largest industries in terms of employment tended to have the smallest percentage revisions.

Sources of the difference. Differences between the benchmark totals and the sample-based estimates are caused by both sampling and nonsampling error. Sampling error may occur whenever inferences are drawn from a sample about its universe.

Nonsampling error has three major sources: (1) bias, (2) procedures for handling changes in industrial classification, and (3) other errors of coverage, response, processing, and collection. Bias is inherent in establishment surveys largely because sample estimates do not readily capture employment growth from new firms. The survey's sample design also places a higher probability of selection on firms with greater employment. This too creates a bias problem, because small, young firms are responsible for much of employment growth. Coincident with this benchmark, the Bureau is introducing increased sample stratification by establishment size for trade and service industry estimates. With finer stratification by size, there is an increase in the relative weight assigned to small firms during estimation, thus lessening the large firm bias.

Revisions to other data. Benchmarks are not available for the series on women, production or nonsupervisory workers, or hours and earnings. Women and production worker series are revised by applying the sample-derived ratio to the revised employment estimate at the basic cell level. These revisions are then summarized to the broader industry groupings.

Production and nonsupervisory worker employment estimates are used as weights in the estimation of hours and earnings at aggregate industry levels. Benchmark revisions to employment may cause shifts in these weights, affecting summary level estimates of hours and earnings. This year, the introduction of a new stratification pattern in trade and services has resulted in a slightly larger than usual hours and earnings revision.

Seasonal adjustment. Each year, employment, hours, and earnings data from the new benchmark are incorporated into the calculation of new seasonal adjustment factors. The Bureau uses the X-11 ARIMA seasonal adjustment method, an adaptation of the standard ratio-to-moving average method, which provides for "moving" adjustment factors to take changing seasonal patterns into account.

Revised estimates for employment, hours, and earnings by detailed industry appear in the June issue of *Employment and Earnings*, along with a more complete explanation of the benchmarking procedure and the new seasonal adjustment factors that will be used for the period April 1986–March 1987. Estimates reflecting the new benchmark will appear in the Current Labor Statistics section of the *Monthly Labor Review*, beginning with the July issue. ☐

Deindustrialization and the shift to services

Does the employment shift to services imply that the U.S. is losing its industrial base? Data show the industrial sector as a whole in healthy shape, but a few manufacturing industries in deep trouble

RONALD E. KUTSCHER AND VALERIE A. PERSONICK

Much discussion and concern recently has been focused on the deindustrialization of the United States and the need for a national industrial policy.[1] The well-reported growth in employment in the service sector and the relative decline in employment in manufacturing industries implies to some a decrease in our industrial capacity. The deindustrialization argument points to a lack of investment in basic production, plant closings and layoffs, and the large negative merchandise trade balance as evidence that the United States is losing its manufacturing base.

But precisely how can deindustrialization be defined? Does the shift to a service economy imply the erosion of an industrial base? Should deindustrialization be described as a loss of manufacturing jobs or should production changes also be a criterion? Should these changes be measured in absolute terms or relative terms? These are some of the questions we examine in this article by reviewing data on both employment and production for manufacturing and other major sectors, first as a whole, and then for detailed industries.

Our findings indicate that the shift to a service economy is not really evidence of a declining industrial base, or "deindustrialization." The shift has largely been a relative one. Employment in the manufacturing sector in absolute terms has not declined appreciably over the last two decades (except cyclically), and the most recent projections by the Bureau of Labor Statistics show manufacturing employment recovering most of its current recession-related losses. Furthermore, while employment in manufacturing is still off its previous peak, the same is not true for output. Manufacturing production in real terms has bounced back from the recession and by 1984 had reached a new peak level, hardly proof of a loss of our industrial base.[2]

While little evidence of deindustrialization is present at the macro or aggregate level, an additional finding is that for about 20 manufacturing industries, including steel, leather, and tires, the past 15 years have seen steady declines in both output and employment. Further, the BLS projections for these industries indicate little prospect for recovery. Thus, while it is possible to say from the data we have examined that the United States is not deindustrializing, this is not to conclude that declines in both production and employment have not hit certain industries particularly hard.

Although it is clear that there is little consensus on what is meant by deindustrialization, certain points in these discussions seem more important than others:

- Industrial base to most means the manufacturing sector.
- An absolute decline is more serious than a relative one.
- Production declines are a more alarming signal of a reduction in the industrial base than employment declines, because through efficiencies it is possible to have increasing output with stable or declining employment. Absolute

---

Ronald E. Kutscher is the Associate Commissioner for the Office of Economic Growth and Employment Projections, Bureau of Labor Statistics. Valerie A. Personick is an economist in the same office.

declines in production may result from many factors, such as increasing competition from other products or from foreign producers, or a lack of capital investment. In this article, we only examine the observed production changes without looking at the reasons why.

- Production should be measured in quantity or real terms to eliminate price effects.

Macro review

Shifts in employment. We begin this examination of America's possible deindustrialization by reviewing employment changes at the macro or most aggregate level over the past 25 years. Our analysis of data on changing job shares clearly indicates significant structural change occurring in the U.S. economy. Does this imply that the United States is losing its industrial capacity?

The goods-producing sector is defined here to include manufacturing, construction, mining, and agriculture; service-producing includes all other industries, including government. While beginning the overview of employment at the broad aggregations of goods-producing and service-producing, this article will focus more on manufacturing, because as noted earlier, this is the sector with which the deindustrialization argument is most concerned.

The first point to be made is that the shift to services has been largely a relative shift and not an absolute one. Job gains in service-producing industries were not accomplished at the expense of any of the major goods-producing industries, except perhaps agriculture. Rather, employment has remained fairly stable in the goods-producing sector as a whole, including manufacturing, while increasing sharply in the service-producing sectors, as chart 1 shows. The stability in the level of jobs in the goods-producing sector and in manufacturing is evident throughout the 1959–84 period, except for times of cyclical decline such as 1974–75 or 1980–82.[3]

The point that the employment shift to services has largely been only a relative one has also been made by Bureau economist Michael Urquhart in a 1984 *Monthly Labor Review* article.[4] His examination of labor force data over the period of 1969 to 1979 showed that there had been no real net migration of workers from the goods to the services sector, but rather most of the growth in service sector jobs was attributable to the increase in women's labor force participation.

Despite the overall stability in the absolute number of goods-producing jobs, the change in shares between the goods- and service-producing sectors has been dramatic. In 1959, the latter sector accounted for 60 percent of all employment and the former, 40 percent; by 1984, that ratio had shifted to 72 percent of employment in the service-producing sector and only 28 percent in the goods-producing sector. (See table 1.)

1979–84	1.0	−1.1	−0.3	−1.6	0.1	−1.6	−2.0	−0.9	1.9	0.0	2.5

NOTE: Data include wage and salary, self-employed, and unpaid family workers.

For manufacturing alone, the share decline has not been as sharp, but still significant. While remaining fairly level at about the 19 to 20 million mark for the past two decades (except for the recessionary periods noted earlier), manufacturing employment fell from 25.1 percent of all jobs in 1959 to 18.5 percent in 1984. It is this widely reported decline in job share for manufacturing, along with reports of plant closings and high regional unemployment in some heavy manufacturing centers, which may have fostered much of the concern about a loss in our industrial base. Of course, these declines have resulted in many hardships among the workers displaced.[5]

The difference between a 12.3-percentage-point share loss for the goods sector as a whole between 1959 and 1984 and only a 6.6-percentage-point drop for manufacturing by itself is accounted for mostly by the loss of agricultural jobs. Agriculture was the only goods-producing sector to register actual employment decreases over the period. The agricultural sector has been shrinking dramatically since at least the 1940's. Low farm prices during the Great Depression of the 1930's eliminated many farm jobs and forced rapid consolidation, eventually leading to very high productivity gains in farming. The movement away from the farm gradually began to taper, and in the past decade the decline in agricultural employment has slowed appreciably.

It has also seemed that the shift to services has accelerated in recent years because of the 1980-82 recessions and because of the increase in imports, especially of manufactured goods, resulting in part from the high value of the dollar. Employment in the goods-producing sector declined by 3 million from the pre-recession 1979 level to 1983's trough, while service-producing jobs increased every year during that time span, by a total of 4.1 million. Of the 3-million loss in jobs in the goods-producing sector, 2.6 million were in manufacturing, and only small amounts were in the other goods-producing components. Goods-producing employment recovered somewhat in 1984, rising 1.4 million, but this gain was dwarfed by the almost 3.0 million new service-producing jobs added in that single year. Within the goods sector, construction employment recovered to its pre-recession high, but manufacturing employment was still off 1.6 million.

Thus, from an employment perspective, there clearly has been a large *relative* decline in the share of employment in goods-producing industries and a similar *relative* decline in manufacturing. However, in absolute terms the employment levels in all goods-producing sectors except agriculture were relatively stable prior to 1979, and even increased in construction. Since 1979, manufacturing employment has declined appreciably, however, and only part of the cyclical losses of 1980–82 have been recovered to date.

Shifts in output. As noted, it may be more important for an examination of the deindustrialization debate to review production rather than just employment, on which most of the debate seems to have focused thus far. A decline in employment, whether absolute or relative, need not necessarily signify an erosion of the U.S. industrial base if real output is still increasing. Using production as a criterion, the goods-producing sector, by reaching new peak levels in 1984, has clearly shown that it is not disappearing. In addition, although a shift away from goods production in relative terms has occurred, it can be seen from chart 2 that the magnitude of that relative shift is less for output than it is for employment. The goods-producing sector accounted for 54.9 percent of the real value of all production in 1959 and 46.7 percent in 1984, a drop of 8.2 percentage points. (See table 2.) The decrease in its job share over that span, however, was 12.3 percentage points. This differential comes about because productivity gains, although slowing down over time, have been more rapid in the goods-producing than in the service-producing sector.

These conclusions relating to output are based on data computed for the Bureau's economic and employment projections system.[6] Actual production, rather than sales in nominal dollars, should be the basis for this analysis, because different price movements among goods and services can distort actual production changes. However, it is impossible to measure the output of many industries' goods or services in actual production units.[7] A proxy for production that is widely used is sales or shipments in nominal prices, deflated by a price index appropriate to the particular industry's mix of goods and services. These data on real output, as well as data on employment, are available for each of 150 individual industries encompassing the total U.S. economy. Historical data are available from 1958 to 1984 and projected data through 1995.

Another conclusion drawn from looking at this data base is that more of the relative decline in goods-sector output is attributable to agriculture and construction than to manufacturing. In contrast, the loss in employment share occurred primarily for the agriculture and manufacturing components of the goods-producing sector. Manufacturing dropped 6.6 percentage points in its job share between 1959 and 1984, but only 2.3 points in its output share.

The trend for only the more recent 1979–84 span is also more positive for output than it is for employment. By 1984, goods-producing output in constant dollars had recovered from the 1980–82 recessions, surpassing the previous peak reached in 1979 and hitting an all-time high. As mentioned, employment in the goods-producing sector has also recovered from the 1980–82 downturns, but not enough to regain the 1979 level.[8]

Again, the more important point is whether a *relative* decline reflects the erosion of our industrial sector. If manufacturing production is still growing in absolute terms, then we cannot be said to be eliminating our industrial base, even though we are undergoing a relative structural shift in our economy. The data at the aggregate level for each of the major sectors show production levels for all compo-

nents growing in absolute terms. Real output in manufacturing in 1984 was actually more than double what it was in 1959—hardly evidence of a reduction of an industrial base. The impression that deindustrialization has accelerated recently because of the recession is also questionable. Real manufacturing output did drop by almost 13 percent over the 4 years from the 1979 peak to the 1982 trough, but in the 2 years since, it has gained almost 18 percent, surpassing the 1979 level. However, when looking at recent employment trends, the story differs. Manufacturing employment reached its low point in 1983, and in 1984, although 1 million jobs were added, it did not recover to the 1979 peak. Furthermore, preliminary data for 1985 indicate that little further gains in manufacturing employment have occurred. Thus, output increases have been made without corresponding increases in employment, the result of productivity gains. This loss of manufacturing jobs is a severe problem for certain industries and locales; however, the rise in manufacturing output overall seems to preclude a conclusion of deindustrialization—at least at the level of total manufacturing.

Another argument advanced in the discussion about deindustrialization is that the U.S. manufacturing sector has performed poorly in comparison with other industrialized countries. However, the evidence to support this impression is mixed. A recent Bureau study of manufacturing productivity trends in 12 countries shows that while the rate of gain in U.S. manufacturing output over the years 1973–84 was smaller than for four of the other countries, particularly Japan, the rate of employment decline in U.S. manufacturing was the smallest of any of the countries studied.[9]

Hours. Another point to be made about the shift to services at the major sector level concerns hours. Because at least part of the growth in employment in the service-producing industries has been in part-time jobs, the amount of the shift can be overemphasized by looking only at employment. The share of worker-hours in the goods-producing sector dropped from 41.1 percent of the total in 1959 to 30.3 percent in 1984, or 10.8 percentage points. (See table 3.) This relative shift in hours is less than for employment, but more than for output.

Quality of jobs. One reason for the concern in the popular literature about the shift away from manufacturing industries toward service-producing industries, especially for employment, is the fear that this will lead to the disappearance of well-paying factory jobs. It is argued that the declining smokestack industries have a large proportion of middle-income earners, while the growing service and high-tech industries have a more bipolar wage structure, with more high or low earners. The shift among industries, therefore, will lead to a declining middle class.

Considerable doubt has been cast on this argument, however, by Neal Rosenthal in a previous *Monthly Labor Review* article.[10] He found through an analysis of occupational data that while middle-income jobs have declined slightly as a percentage of total employment, lower-paying jobs have declined even more. Furthermore, declines in high-paying smokestack industries (such as steel) have at least been matched by declines in lower-paying manufacturing industries (such as textiles, apparel, and leather).[11]

Micro analysis

Industry shifts. In the above section, we discussed output and employment at the major sector or very aggregate level. At that level we showed that while the U.S. economy in relative terms is shifting in a very pronounced way towards the service-producing sector and away from the goods-producing sector, in absolute terms the manufacturing sector is nearly stable in jobs and growing in production—giving little evidence of a loss of the U.S. industrial base. However, this examination at the macro level could be masking important changes at the micro or industry level. In this section, we examine some of these divergent employment and output trends for individual industries, using the level of detail in the BLS projections system.

In reviewing these industry output and employment data closely for the period 1959–84, it appears that the time frame 1959–69 is quite different in its characteristics from either the 1969–79 or 1979–84 span. During the booming 1960's, manufacturing increased its share of output and held steady in its share of employment, whereas after 1969, several recessions and other factors forced manufacturing off its earlier upward path. Economic downturns in 1970, 1974–75, and 1980–82 had a larger impact on the cyclically sensitive manufacturing sector than on the more cyclically resistant service-producing sector. Because of the different characteristics of the earlier years, the analysis in this section of the article will focus on the more recent 1969–84 period. The analysis consisted of examining industries over the 15-year span and categorizing them into 1 of 3 groups: (1) consistent gainers in output and employment, (2) consistent gainers in output but employment losers, and (3) consistent losers of both output and employment.

Output and employment gainers. Table 4 lists those industries which have shown a positive trend in both output and employment during the last 15 years. (That is, the least squares rate of change over 1969–84 has been positive. This does not mean that these industries may not have shown declines for a few of the years but only that the overall trend for the span is positive.) One-half of the 150 industries in the data base examined fall into this category. Among the goods-producing industries which are included in the growing industries are 4 of the 7 agricultural industries, 2 mining industries, maintenance construction, and numerous manufacturing industries. Most of the latter on the list of output and employment gainers are durable goods industries, particularly those which are included in 1 of the 3 high-technology definitions developed earlier by BLS.[12] These designations identify high-tech industries on the basis of expenditures for research and development, the ratio of scientific and technical personnel to all workers in the industry, and the degree of product sophistication. Many of the electrical machinery and electronic equipment industries which meet one of the high-tech definitions have experienced both production and employment advances in the last 15 years.

The rest of the industries on the list include virtually all of the individual service-producing industries in the data base. Only a few of the transportation industries, gas utilities, or service industries have lost either jobs or production, or both, between 1969 and 1984. All the communications

[1] Based on least squares trend line.

n.e.c. = Not elsewhere classified.

industries, electric and water utilities, trade, finance, and most other service industries have had positive trends in both output and employment during the last 15 years.

Of course, even within services, some industries have not grown as rapidly as others. The biggest gainers in both output and employment were business services and medical services. Personal services and private educational services, in contrast, have posted only moderate growth.

Output gainers and employment losers. In the second category of industries selected in our review process are 37 of the 150 industries in the data base. These industries have experienced real production increases between 1969 and 1984 but have had declining job trends. (See table 5.) This category still could indicate relatively healthy industries, where greater efficiency has allowed more output to be produced with fewer workers. Many of the food processing, textile, chemical, metal products, and industrial machinery industries are on this list, as well as motor vehicles. Demand for these products continued to be strong, but new manufacturing technologies or better use of existing technologies permitted increases in production with less employment.

Output and employment losers. Finally, table 6 shows those industries which have declining trends for both production and employment over the 1969-84 period, 24 in all. Chart 3 graphs that decline for a few of these industries. Most of the industries included in table 6 are those well-recognized as having long-term problems. The steel industry, for example, began its decline long before the last recession. Because of large international wage differentials and the failure to invest in more efficient new technologies, the domestic steel industry lost out to cheaper-priced imports or to substitute materials, especially after the energy crisis in 1973–74 forced transportation equipment manufacturers and others to turn to lighter-weight materials. Other industries on this list of output and employment losers have also faced either declining demand for their products or stiff competition from imports or both, leading to a long-run decline. Included would be some of the mining industries, tobacco, leather products, rubber, wooden containers, metal cans, and watches and clocks.

The troubled industries listed in table 6 lost a combined total of 1.5 million jobs between 1969 and 1984, but of that total, two-fifths was in one industry, the private household industry—and that industry, of course, is not considered part of our industrial base. Of the rest of the troubled industries, blast furnaces and basic steel products dominates in terms of both output and employment lost. The job decline in this industry totaled .3 million between 1969 and 1984, (one-fifth of the total loss for all troubled industries), and production losses were 34 percent. Other industries in table 6 with more than a 20-percent reduction in output over the 15-year span included iron and ferroalloy ores mining, copper ore mining, wooden containers, rubber products except tires, leather tanning and finishing, leather products (mainly shoes), primary nonferrous metals and products, heating equipment and plumbing fixtures, railroad equipment, and watches and clocks. Combined, the troubled industries in table 6 accounted for 6.7 percent of total real production in the economy in 1969, but by 1984 they had declined to only 3.7 percent. For jobs, the share drop was equally sharp—from 6.0 to 3.1 percent. For the manufacturing industries only among the group of output and employment losers, output dropped from a 6.1-percent share in 1969 to 3.4 percent in 1984, and employment from 3.5 to 1.8 percent. Thus, while we have shown that restructuring does not necessarily mean "deindustrialization" or the loss of an industrial base at the macro level, these data clearly isolate a group of individual industries within the manufacturing sector which are in deep trouble.

Recent problem industries. In addition to the long-term declining industries, several other manufacturing industries seem to have been hit especially hard in the 1980–82 recessions and have not recovered previous production or employment levels. Many machinery producers in addition to those listed in table 6 are in this category, along with basic chemicals, construction-related industries, and some textile industries (but not apparel). The construction-related industries showed good output growth in 1984, however, and are on their way to surpassing 1979's peaks. The chemical, textile, and many of the metals and machinery industries also showed gains in 1984 and may be expected to eventually fully recover. The exceptions are nonferrous metal ores mining, petroleum refining, and miscellaneous manufactured products. Demand for these items has not picked up much, and output is still depressed. Also, although all the metal and machinery industries did experience production upturns in 1984, the recovery was weak for many and they are still far from pre-recession levels. Examples not already identified as long-term losers include fabricated structural metal; cutlery and handtools; engines and turbines; farm and garden machinery; construction, mining, and oilfield machinery; electrical transmission equipment; and electrical industrial apparatus. For all of these industries, as well as several on the long-term declining list, production in 1984 was still at least 10 percent below pre-recession levels.

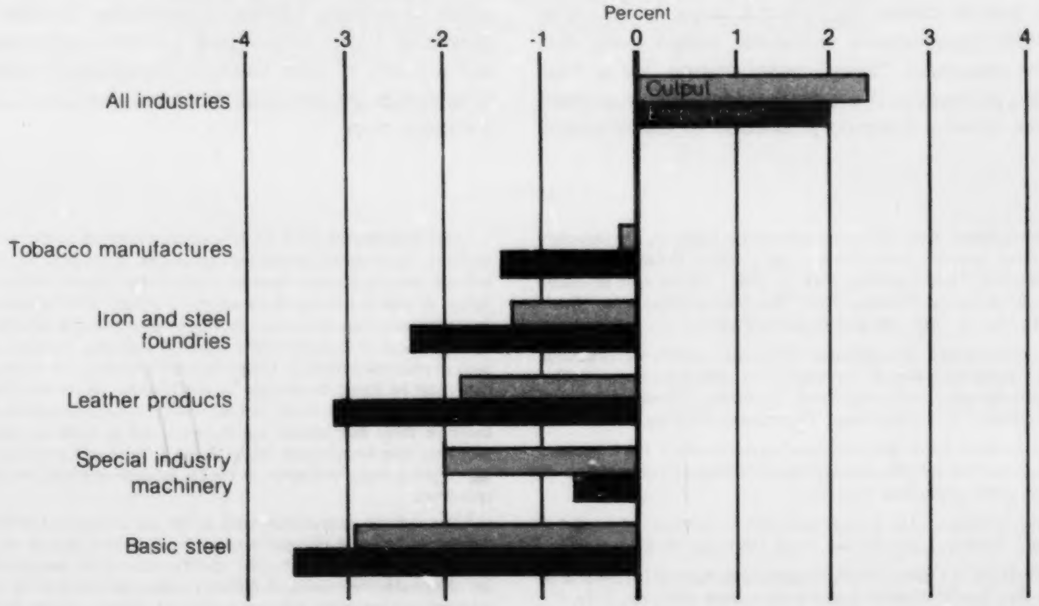
Outlook for the future

BLS projections of output and employment, published in the November 1985 *Monthly Labor Review*, indicate that the goods-producing sector (under the assumptions of the middle projections scenario) is expected to grow in absolute terms in both production and jobs, but to continue to decline as a share of total. The share decline will be more rapid for employment than for output. The goods-producing sector is projected to gain 1.8 million jobs by 1995, but drop from 27.7 percent of all jobs to just 25.6 percent. Production in goods-producing industries, in contrast, is projected to almost keep pace with total output growth, and the decline in the goods-producing share of output will be smaller than for employment.

The decrease in the total employment share projected for the goods-producing sector will be concentrated in agriculture, mining, construction, and nondurable manufacturing industries. Durable goods industries, however, are projected to account for greater shares of both output and employment in 1995, contrary to past trends. This results from the macroeconomic assumptions of strong growth in capital spending for producers' durable equipment, continued increases in defense purchases, and relatively faster growth in exports than in imports of manufactured capital goods as the high value of the dollar continues to fall. Productivity is also projected to increase over the next 10 years, but demand for durable manufacturing products is projected to be high enough to stimulate job growth.

A look at the BLS individual industry projections reinforces the conclusion that the goods-producing sector and manufacturing in particular will not be shrinking in absolute terms. (See table 7.) Among the top 15 fastest-growing employment industries projected, 8 are in manufacturing, and for output, that figure is 11 of 15. The manufacturing industries on these lists of fastest-growing output and employment reflect the assumptions of strong demand for sophisticated capital equipment, medical supplies and drugs, and defense materiel.

Chart 3. Output and job trends, selected long-term declining industries, least squares rate of change, 1969-84



The outlook for the troubled industries identified in table 6 is not so rosy. Some of the industries experiencing long-term loss of markets are projected to continue their decline through 1995. Some small production increases are expected for the steel industry, but only if more efficient technologies are implemented. Employment in steel is projected to drop by more than 20 percent between 1984 and 1995. No production comebacks are anticipated for wooden containers, leather products, tobacco, or the household industry.

Some of the machinery and defense-related sectors on the list, however, are projected to reverse trend and rebound from current low levels. Demand for materials handling equipment is projected to be so strong as to rank that industry among the top 10 in terms of projected output growth. This turnaround is expected to occur as many factories add new, highly engineered, computer-controlled production systems, incorporating industrial robots and automatic material handling.

Table 7. Fastest-growing employment industries and output industries, 1984–95

OUR ANALYSIS HAS SHOWN that while there has clearly been a long-term employment shift to the service sector, that shift has for the most part been a relative shift only, and not an absolute one. Only with the last cyclical downturn did the manufacturing sector fail to hold a steady job level. Furthermore, the relative shift to services has been far less pronounced for output than for employment, and manufacturing production has even been growing in absolute levels. While some manufacturing industries clearly have been in a long-term decline, and the 1980–82 recessionary period may have exacerbated their problems, our data indicate that the United States is not losing its industrial base. Most manufacturing industries, indeed many that would be considered "heavy" manufacturing, are at least expanding production, if not employment. Higher productivity has allowed domestic production of manufactured goods to increase without corresponding increases in employment. Future expenditures for new capital equipment and a return to more balanced international currency exchange rates are projected to boost demand for U.S. goods for many years. □

[6] For a description of the output data and the latest projections, see "Employment Projections for 1995: Data and Methods," BLS Bulletin 2253, March 1986.

[7] One limitation in the type of analysis presented in this article is the difficulty of accurately measuring real output. When possible, real output is based on some physical measure of production, such as units in manufacturing, or tons in mining, or passenger- or freight-miles in transportation. In many cases, however, output data are based on sales or receipts, deflated by a producer or consumer price index, if available. In some industries, such as noncommercial (or nonprofit) establishments, for example, output data must be based on changes in employment. When the data are this limited, any measure of productivity change is very questionable. Presentation of these data should not be interpreted to mean all measurement problems have been solved. Many difficult issues still remain for measuring output in many industries, as well as measuring price changes in those industries.

[8] The industry output data used in the BLS projections system can be defined as "gross duplicated output," because they include not only the value added in each industry but also the value of all intermediate inputs into the production process. A different definition of output, "gross product originating," measures just that portion of industry output that is value added, that is, labor compensation, profits, rents, interest, and indirect business taxes. This latter measure for all industries sums to Gross National Product (GNP).

Gross product originating, or value added, is not used in the BLS model system for several reasons. For one, it is not available for detailed industries. In addition, total or duplicated output is probably a better variable to use in estimating each industry's demand for labor than just the value-added portion of output. Duplicated output can be more closely related to total demand for an industry's products, whether the demand is from final consumers or from intermediate producers.

Gross product originating data can be used to analyze broad sectoral shifts, however, and the results are quite similar to those just described using duplicated output data. Because the former type of data excludes all intermediate products, for each year the percent of total output (or GNP) accounted for by the goods-producing sector is smaller than the percentage based on gross product originating data (which double counts the value of intermediate inputs, more of which are goods than services). However, over time the percentages for both types of data in the goods-producing sector have declined about the same relative amount.

As noted, the goods-producing gross duplicated output share fell from 54.9 percent of total output in 1959 to 46.7 percent in 1984, a loss of 8.2 percentage points. The gross product originating share fell from 37.8 percent to 32.6 percent, or 5.2 percentage points. However, employment fell from 40 to 27.7 percent, a drop of 12.3 percentage points. Thus, no matter which measure of output is used, the shift between goods- and service-producing industries has been considerably less pronounced for output than it has been for employment.

A note on communications

The *Monthly Labor Review* welcomes communications that supplement, challenge, or expand on research published in its pages. To be considered for publication, communications should be factual and analytical, not polemical in tone. Communications should be addressed to the Editor-in-Chief, *Monthly Labor Review*, Bureau of Labor Statistics, U.S. Department of Labor, Washington, D.C. 20212.

Consumer expenditures: results from the Diary and Interview surveys

Data from the Consumer Expenditure Survey show that urban consumers spent about two-thirds of their total expenditures on food, housing, and transportation

RAYMOND GIESEMAN AND JOHN ROGERS

Historically, the Bureau of Labor Statistics Consumer Expenditure Survey has been of importance largely for its role in periodically revising the Bureau's Consumer Price Index. Results from the survey are used to select new market baskets of goods and services for the CPI, and to determine the relative importance of the items selected. While this remains an important use of the Consumer Expenditure Survey, the increasing demand for more timely information about the spending habits of different kinds of households has expanded the role of the survey, making it an important source of information in its own right.

In the past, the expenditure survey was conducted about every 10 years, the previous one being in 1972–73. However, sharp increases in the costs of energy and housing during the 1970's highlighted the need for timely expenditure data in order to observe consumers' response to these phenomena. The BLS recognized the need for a survey that would provide a continuous flow of data, and began the current survey in 1980. Data from this ongoing survey allow analysts to track expenditures classified by household characteristics over a period of time and to link expenditure changes to changes in economic and social conditions. Among the characteristics by which the expenditures may be classified are: before-tax income, consumer unit size, age of reference person, region of residence, and number of earners.[1]

Data from the 1982–83 Survey of Consumer Expenditures show that urban American consumers spent about two-thirds of their total expenditures on food, housing, and transportation; they spent more than a third of their food dollar on food away from home; and average transportation expenditures increased 7 percent from 1980–81 to 1982–83, despite a 10-percent decline in gasoline expenditures. These are among the results that the Consumer Expenditure Survey provides and that this article describes.

Description of the survey

The expenditure survey consists of two separate components, each with its own questionnaire and sample: a quarterly interview survey in which each of the sampled consumer units reports information to an interviewer every 3 months for five consecutive quarters, and a diary survey in which consumer units are asked to complete a diary of expenses for two consecutive 1-week periods. At the same time, a great deal of information is obtained about the characteristics of the members of the consumer unit. The Interview survey is designed to obtain data on expenditures and income that respondents can be expected to recall for a period of 3 months or longer, such as property or automobile purchases, and those that occur on a regular basis, such as rent, utility bills, or insurance premiums. It is estimated that about 95 percent of expenditures are covered in the Interview survey. The Diary survey obtains data on frequently purchased items such as food and beverages, housekeeping supplies, and so forth, that respondents are less likely to be able to recall over long periods of time. Expenditures incurred away from home overnight or longer are excluded from the Diary survey. Spending on trips is obtained in the Interview survey. To obtain a complete picture of consumer spending, it is necessary to integrate results from both survey components. Data collection for both components of the

survey is carried out by the Bureau of the Census under contract to the Bureau of Labor Statistics.

Average expenditure levels

Expenditures and income of consumer units classified by five household characteristics—income quintile, age of reference person, region of residence, size of consumer unit, and number of earners—are shown in tables 1 and 2. Table 1 includes Interview survey data and table 2 shows Diary survey data for 1982–83. The tables also include the number of consumer units and average consumer unit size for each class.

The interview data show that expenditures can vary substantially when classified by different consumer unit characteristics. The amount spent for food and housing by consumer units in the highest income quintile was more than three times the amount spent by those in the lowest income quintile. Consumer units with reference persons aged 65 and over spent four times as much on health care as those with reference persons under 25 years of age. Consumer units in the West spent 20 percent more on average for transportation than those in the Northeast, and four-person consumer units spent twice as much on housing as single persons.

Results from the Diary survey show that consumer units in the highest income quintile spent more than 2½ times as much on food at home as the lowest income quintile consumer units, and more than 4½ times as much on food away from home. Consumer units whose reference person was under 25 years of age spent about 38 percent less for food at home than those with reference persons over 65 years of age, but spent 48 percent more for food away from home. Consumer units in the South spent about 11 percent less for food than those in the Northeast.

Budget shares

While actual expenditure levels are revealing to some users, others may find budget shares more appropriate. Budget shares are the portion of total expenditures spent on a component or the portion of an average component expenditure spent on a subcomponent.

For example, the interview data show that the highest income quintile consumer units spent more than three times the amount for food and housing than did those in the lowest quintile, but that amount accounted for only a 44-percent

Table 1. Average annual income and expenditures by selected household characteristics, urban United States, Interview survey, 1982–83

Characteristic	Number of consumer units (thousands)	Income before taxes[1]	Consumer unit size	Expenditures

Three or more earners	7,260	38,130	4.6	29,556	5,445	7,511	1,742	6,545	1,068	1,383	2,964	2,896

[1] Includes only consumer units providing complete reports of income.

share of their total expenditures, compared with a 58-percent share of the total for those in the lowest quintile. Almost 10 percent of the total expenditures of consumer units with reference persons aged 65 and over were spent on health care, compared with less than 3 percent spent by those with reference persons under 25. The youngest consumer unit class spent 23 percent of their total on transportation, compared with 16 percent spent by the oldest class of consumer units. Food and housing expenditures accounted for a relatively constant share of total expenditures across consumer unit size classes. Single persons spent 51 percent of their total on food and housing, two-person consumer units spent about 48 percent, and shares for other size classes fell within that range.

The diary data show that consumer units spent over a third of their total food dollar on food away from home. The youngest class of consumer units spent about 47 percent of their food dollar on food away from home, compared with only 27 percent for the oldest class.

Food expenditures away from home were also influenced by the number of wage earners in the consumer unit. Single-person consumer units in which the individual was not a wage earner—primarily elderly persons—spent 31 percent of total food expenditures away from home, compared with 58 percent for those in which the individual was a wage earner. Consumer units of two or more persons with no wage earner spent 23 percent of their food budget away from home, compared with 30 percent for those with one earner, and 37 percent for those with two earners.

Income also influences expenditures for food away from home. Consumer units in the lowest income quintile spent 30 percent of their total food expenditures on food away from home, compared with 42 percent for those in the highest quintile. For the middle income quintile, the proportion was about 33 percent.

Aggregate expenditure shares

Some users of expenditure data may be interested in the aggregate amount spent on a component by a particular class of consumer units. Or they may be interested in the portion that amount is of aggregate spending by all consumer units. For such users, aggregate expenditure shares are another

Table 2. Average weekly income and expenditures by selected consumer unit characteristics, urban United States, Diary survey, 1982–83

way of analyzing the consumer expenditure data.

Aggregate expenditures on a component are determined by multiplying the mean expenditure on that component by the total number of consumer units. The aggregate expenditure share of a class of consumer units is determined by multiplying the class's mean expenditure on the component by the number of consumer units in the class and dividing by the aggregate expenditure. This differs from the budget share of a class of consumer units which is the average amount spent on a component as a portion of the average total expenditures of the class. Even though the class's component budget share may be large, the aggregate expenditure share will be relatively small if the class size is small or the class mean expenditure for the component is low relative to that of other classes. For example, the interview data show that consumer units with reference persons under age 25 spent 23 percent of their average total expenditures on transportation, compared with 20 percent spent by all consumer units. However, because the dollar value of their mean expenditure is low relative to most other classes, the aggregate expenditure share for units in the under-25 class was only about 7 percent of total aggregate transportation expenditures, although they account for 10 percent of the total number of consumer units.

The Diary survey data show that consumer units with reference persons age 65 or over had an aggregate expenditure share for food of 13 percent even though the class made up about 19 percent of the population. When classified by income quintile, each income class has a 20-percent population share (of complete income reporters), but aggregate food expenditure shares varied from 10 percent for consumer units in the lowest quintile to 32 percent for those in the highest quintile.[2] By size of household, one- and two-person households accounted for 43 percent of aggregate food expenditures, but 51 percent of aggregate expenditures for food away from home. By age of reference person, consumer units with reference persons age 65 or over accounted for 21 percent of aggregate expenditures for nonprescription drugs and supplies, compared with 3 percent for consumer units with reference persons under 25.[3]

Per capita expenditures

Average consumer unit size varies by classifications of consumer units according to age of reference person, number of earners, and so forth. It may be useful to also consider per capita expenditures because consumer unit size may contribute to differences in expenditures among classes.

For age classes, mean expenditure levels per consumer unit generally increase with age until they peak in the middle age classes, then decline. However, per capita expenditures show a different pattern. Per capita expenditures for housing are highest, $2,425, for the age class with reference persons age 65 or over, compared with the lowest per capita housing expenditure of $1,894 by consumer units with reference persons under 25.

Data from the Diary survey show that expenditure levels for food at home are highest for age classes with reference persons ages 35 to 44 and 45 to 54. However, the highest per capita expenditures are for those classes with reference persons ages 55 to 64 and 65 or over. Average expenditures for nonprescription drugs and supplies are highest for the class with reference persons ages 45 to 54, but per capita expenditures are highest for the class with reference persons age 65 or over.

Expenditure changes over time

Consumer Expenditure Survey data are used to document changes in the expenditure patterns of American consumers over a period of time. Changes in expenditure patterns can be attributed to such factors as shifts in relative prices and wage rates, changes in tastes and habits, changes in lifestyles, and the availability of new products. [2] Income before taxes is calculated using complete income reporters.

[3] Estimated.

graphic trends such as changes in average family size, age, and earner composition can also affect expenditures. The current, ongoing survey allows users to recognize trends more quickly than was possible in the past, and to identify trends that might have been missed altogether using data that were only infrequently available.

Tables 3 and 4 show Interview and Diary survey results from 1972–73 and 1982–83 and percent changes between the two periods. Also shown are CPI changes. The interview data show that gasoline and motor oil expenditures increased 166 percent from 1972–73 to 1982–83, while total expenditures rose 103 percent. This reflects the large increases in energy costs in the 1970's resulting from oil price increases. While the increase in gasoline and motor oil expenditures was somewhat higher than the increase in total expenditures, it was still well below the 232-percent price rise measured by the CPI. That was the result of consumers modifying their behavior in response to price increases by reducing their gasoline and motor oil consumption, and adjusting their longer term buying habits, as by purchasing more fuel-efficient automobiles.

Table 4. Characteristics and average weekly expenditures of urban consumer units, and percent change in consumer expenditures, Diary survey, and Consumer Price Index, July 1972–June 1974 and 1982–83

Item	July 1972–June 1974	1982–83[1]	Percent change	
			Consumer expenditures	CPI
Number of consumer units (in thousands)	59,159	71,356	—	—
Consumer unit characteristics:				
Income before taxes[2]	$187.46	$427.21	128	—
Size of consumer unit	2.8	2.6	—	—
Age of reference person	47.1	46.4	—	—
Number in consumer unit:				
Earners	1.3	1.3	—	—
Children under 18	.9	.7	—	—
Persons 65 and over	.3	.3	—	—
Average weekly expenditures:				
Food, total	$33.11	$56.16	70	104
Food at home, total	23.79	36.32	53	99
Cereals and bakery products	2.79	4.82	73	118

Personal care products and services	2.92	4.53	55	102
Nonprescription drugs and supplies	1.19	1.89	59	103
Housekeeping supplies	2.99	5.55	86	144

[1] Excludes students.

[2] Income before taxes is calculated using complete income reporters.

Although gasoline and motor oil expenditures rose sharply over the decade 1972–73 to 1982–83, they actually decreased by 10 percent from 1980–81 to 1982–83. This recent decline can be attributed to falling prices and conservation measures over that period. These are the kinds of trends that might have been missed had data for 1980–81 not been available.

Diary survey data show that average weekly expenditures for food increased 70 percent between 1972–73 and 1982–83, well below the 104-percent price rise for food measured by the CPI. Expenditures for food away from home increased 113 percent over the period, compared with a more modest increase of 53 percent for food at home. The changes in the expenditure data and the CPI for food away from home were quite similar (113 percent, compared with 120 percent), while there was a sharp difference in the changes for food at home (53 percent, compared with 99 percent).

Between 1972–73 and 1982–83, CPI-measured prices increased more than average expenditures for all food at home categories. Food categories with the largest price increases tended to have the largest expenditure increases. However, prices for meats, poultry, fish, and eggs rose 70 percent, while expenditures for those items rose only 24 percent.

While not presented in this article, expenditure data for specific products and services keep track of the speed with which new products are disseminated. Such data are available on public use tapes. The following tabulation shows mean expenditures from the Interview survey, for selected items:

	1980	*1981*	*1982*	*1983*
VCR	$ 8	$ 10	$ 23	$ 21
Cable TV	31	43	59	79
Child care and babysitting	76	91	91	108

This article has presented some of the ways of analyzing the consumer expenditure data. As speed and efficiency in processing the data improve, the uses of the data and the number of users are expected to multiply. The timeliness of this ongoing survey enhances its application not only in revising the CPI, but also as a valuable information source for public and private analysts examining the relationships of family characteristics, income, and expenditures. ☐

FOOTNOTES

[1] A consumer unit is defined as a single person or group of persons in a sample household, related by blood, marriage, adoption, or other legal arrangement, or who share responsibility for at least two out of three major types of expenses—food, housing, and other expenses.

[2] The distinction between complete and incomplete income reporters is based in general on whether the respondent provided values for major sources of income, such as wages and salaries, self-employment income, and Social Security income. Even complete income reporters may not have provided a full accounting of all income from all sources.

[3] For a more detailed discussion of aggregate expenditure shares, including data tables, see Kirk Kaneer, "Distribution of consumption examined using aggregate expenditure shares," *Monthly Labor Review*, April 1986, pp. 50–53.

BLS area wage surveys will cover more areas

Earnings data for blue- and white-collar occupations will be published for 90 areas instead of the current 70, but about two-thirds of the areas will be surveyed on a 2-year rather than 1-year cycle

LAURA SCOFEA

The Bureau of Labor Statistics will restructure the probability sample of labor markets for its area wage survey program to reflect changes in the number and geographic boundaries of the Nation's metropolitan statistical areas. The new area sample will be phased in over a 4-year period beginning in January 1987, and will contain 90 areas when fully implemented. The 32 largest areas in terms of nonfarm employment will be surveyed annually, and two groups of 29 areas will be surveyed in alternate years.

Currently, 70 areas are surveyed annually. Of these areas, 56 will remain in the program; geographic boundaries, however, will change for 34 of them.

This article gives a brief description of the Bureau's area wage survey program and the changes to be made in the probability sample of areas surveyed. The article covers area wage survey program objectives and program evolution from initial 1947–48 studies of pay for office clerical occupations in 11 large cities. It also describes the metropolitan area concept used in the program, reasons for changes in the area sample, the method for selecting the new sample, and the differences between the old and new area samples.

Program background

The Bureau's area wage survey program is designed to shed light on the level and structure of occupational pay rates within a local labor market by studying occupations common to many industries.[1] The areas surveyed are a representative cross-section of the wide variety of local labor markets found throughout the United States. The surveys, relating to specific payroll periods, focus on pay relationships among occupations, industries, and areas of the country. Successive survey findings are also useful in reviewing pay changes over time.

Using a standard set of job descriptions, the Bureau designs surveys which cover narrowly defined occupations selected from four categories—office clerical (such as secretaries, typists, and accounting clerks); professional and technical (for example, computer programmers and electronics technicians); maintenance, toolroom, and powerplant (maintenance electricians and stationary engineers); and material movement and custodial (order fillers and guards). Estimates of average straight-time hourly or weekly earnings and distributions of workers by their earnings are developed for each of approximately 50 occupations studied. (Fifteen of the occupations—for example, word processors, computer systems analysts, and guards—are divided into two work levels or more.)

In addition, every third year the surveys yield information on the prevalence of provisions for cost-of-living adjustments in pay rates; minimum entrance salaries for inexperienced typists and other inexperienced clerical workers; pay differentials for work on late shifts; work schedules; extent of collective bargaining agreement coverage; holiday, vaca-

---

Laura Scofea is an economist in the Division of Occupational Pay and Employee Benefit Levels, Bureau of Labor Statistics.

tion, and other paid leave provisions; and the incidence of health, insurance, retirement, severance pay, and supplemental unemployment benefits. Data typically are developed separately for production and office workers; information on shift pay differentials, however, is restricted to production workers in manufacturing.

Findings for each area wage survey are published in a separate BLS bulletin.[2] To aid in interarea pay comparisons, average area pay levels in four employment groups—office clerical, electronic data processing, skilled maintenance, and unskilled plant jobs—are related to pay levels for all metropolitan areas combined, in index form, that is, all metropolitan area pay levels = 100. Results are published in an annual summary release.[3] Results of the individual surveys, after appropriate weighting to account for areas not surveyed, are also combined to develop pay levels for the narrowly defined occupations in all metropolitan areas combined; separate data are presented for major industry divisions and for four broad geographic regions.[4] Also, special articles appear in the *Monthly Labor Review*, with in-depth analyses of specific survey findings.[5]

The area wage survey program has grown considerably since it started in fiscal year 1948 as part of a restructuring of the Bureau's occupational wage survey activities. That year's surveys provided information on salaries in office clerical occupations in 11 large *cities*. In 1950, the geographic scope of the surveys expanded from cities to the larger metropolitan areas as defined by the U.S. Bureau of the Budget (now the Office of Management and Budget). A year later, professional and technical, maintenance, and custodial and material movement occupations were added.[6]

These developments roughly coincided with the outbreak of the Korean conflict. Resources for area wage surveys were expanded as a result of this emergency in order to provide data for administering wage stabilization policies. During the 1950's, between 11 and 40 areas of various sizes were studied in a given year, with the number depending on resources available for the program.

Current program emerges

In fiscal year 1960, the current program emerged when there was a conversion from studies in judgmentally selected areas to a statistically selected sample of areas chosen to represent all metropolitan areas in the contiguous 48 States. Consequently, findings of individual areas could be combined, after appropriate weighting, to yield national and regional estimates. The sample selected for fiscal 1960 contained 60 areas, representative of the 188 areas then in the scope of the program. A year later, the sample included 80 areas, and gradually grew to 85 areas, representing the 229 areas in scope for 1969.[7]

The major thrust of the 1960's expansion was a need for nationwide estimates of office clerical pay in private industry for use in evaluating Federal white-collar salaries. Data obtained for plant jobs in the individual areas surveyed also were used by the Department of Defense and other agencies in setting pay rates for their blue-collar "wage board" employees.

The most recent change in the program occurred after the Office of Management and Budget made major changes in its list of metropolitan areas, based on results of the 1970 Census of Population. The Bureau selected a new 70-area sample and introduced it in July 1974.[8] These 70 areas will continue as the area sample through December 1986, representing the 262 metropolitan areas (excluding those in Alaska, Hawaii, and Puerto Rico) recognized and defined by the Office of Management and Budget as of February 1974.

Changing metropolitan area definitions

With few exceptions, area wage surveys have been conducted since 1950 in metropolitan areas as defined by the Office of Management and Budget or its predecessor, the Bureau of the Budget.[9] Standard metropolitan area definitions were first developed by the Bureau of the Budget shortly before the 1950 census, primarily to provide a common set of geographic definitions for Federal statistical agencies.

The metropolitan area concept recognizes that large population concentrations often extend beyond the borders of a single city. Under this concept, a metropolitan area consists of one county or more, containing the area's main population center, and may also include adjacent counties that have close economic and social ties to the central counties. (In New England, metropolitan areas are composed of cities and towns rather than counties.) Areas are designated and defined by the Office of Management and Budget based on a set of criteria developed by the interagency Federal Committee on Standard Metropolitan Statistical Areas.

The number of recognized metropolitan areas has grown substantially, from 172 in 1950 to 288 as of January 1, 1980. In part, this growth stems from changes in the criteria for designating metropolitan areas that have been made at the time of each population census since 1950.[10] Although these changes have not significantly altered the basic metropolitan area concept, they have resulted in the recognition of new areas and in changes in the boundaries of existing areas. However, most of the growth in the number of metropolitan areas is the result of population growth and increased urbanization in the United States.

The most recent revision in standards for designating and defining metropolitan areas was published in the *Federal Register* on January 3, 1980.[11] The new standards introduced revised terminology. The existing term, "Standard Metropolitan Statistical Area" (SMSA), was replaced by "Metropolitan Statistical Area" (MSA) and "Primary Metropolitan Statistical Area" (PMSA). Areas such as San Antonio, TX (Bexar, Comal, and Guadalupe Counties), which are not closely related to other metropolitan areas, and are typically surrounded by nonmetropolitan counties, are called MSA's. PMSA's are components of larger "Consolidated Metropolitan Statistical Areas" (CMSA's). For example, Seattle (King and Snohomish Counties) and Tacoma (Pierce County) are PMSA's that jointly form the Seattle–Tacoma, Washington CMSA. CMSA's, not studied in the area wage survey program, have replaced the former "Standard Consolidated Statistical Areas" (SCSA's).

Restructuring the program

Using the new standards and data from the 1980 census, the Office of Management and Budget defined a total of 326 MSA's and PMSA's in the contiguous 48 States, as of October 31, 1984.[12] As a result, BLS' area sample for its area wage surveys became outdated.

A principal consideration in planning for a revised sample of areas was maximizing the usefulness of survey results, given the level of resources available for area wage surveys. The Bureau and its business and labor advisory groups explored three alternatives: (1) a 70-area sample of the 326 metropolitan areas within the scope of the program, each area to be surveyed annually; (2) a 70-area sample of the 155 areas with populations of 250,000 or more, surveyed annually; and (3) a 90-area sample of all 326 areas, the 32 largest areas of the United States to be surveyed annually and two groups of 29 smaller areas each to be surveyed in alternate years. Each of these options, requiring about the same level of resources annually, was designed to represent areas differing in employment size, industrial composition, and geographic location. Provision for probability sampling permitted the development of national and regional estimates each year as in the past.

The third option was chosen because it provides information for the largest number of areas with the resources available. Also, the burden on individual respondents is reduced by rotating between the two groups of 29 areas.

To select the sample of 90 areas, all 326 MSA's and PMSA's as of October 1984 were grouped into 90 statistical "cells." One area in each of the cells was then selected to represent all areas in the cell. The 32 largest areas in terms of nonagricultural employment were the sole occupants of their cells and thus were automatically included in the sample.

The 294 remaining areas were grouped into 58 (90 minus 32) cells according to the following criteria, which are listed in descending order of importance:

- Broad geographic region—Northeast, South, Midwest, and West;
- Similarity of manufacturing industries (with emphasis on similarity of average earnings of production workers);
- Approximate equality of total nonagricultural employment; and
- Boundaries of BLS regional offices.

One area was randomly selected from each cell. An area's chance of selection was proportionate to its share of the total nonagricultural employment in the cell. For example, an area with a quarter of the employment in its cell had a 1-in-4 chance of selection. A statistical technique known as Keyfitzing was used to obtain as much overlap as possible between areas in the current and new samples.[13]

Exhibit 1 shows the result of the 90-area selection. Fifty-six of the areas in the new sample have been surveyed since 1974; 34 have not. Geographic boundaries stayed the same in 22 of the 56 retained areas; in the remaining 34, new boundaries resulted in nonagricultural employment increases or decreases of fewer than 10 percent in 23 areas; between 10 and 20 percent in 8 areas; and decreases of more than 25 percent in Dallas, Huntsville, and San Francisco. (Decreases in Dallas and San Francisco reflect splits of the former Dallas–Fort Worth and San Francisco–Oakland areas. Two counties formerly in the Huntsville, AL, metropolitan area are now nonmetropolitan counties.)

The new sample, reflecting population shifts in the United States, contains a slightly higher proportion of Southern and Western areas than does the current sample. Among the additions to the area wage survey program are Phoenix, AZ, Riverside–San Bernardino, CA, and Tampa–St. Petersburg–Clearwater, FL, which now rank among the 25 most populated areas.

Implementing the new sample

The 90-area sample will be phased into the area wage survey program over a 4-year period, beginning in January 1987. Each year, surveys will be conducted in 61 areas—the 32 largest areas and half of the smaller areas.

In the largest areas, wage and benefit data will be obtained from surveyed establishments through personal visits by BLS field representatives once every 3 years. In the intervening years, collection (primarily by mail or telephone) will be limited to wage information.

The smaller areas will be divided into two groups of 29 areas. The groups will be surveyed in alternating years. Thus, an individual area will be studied twice in a 4-year cycle: a survey of wages and benefits will be conducted by personal visit one year; and a survey of wages only will be conducted by mail and telephone 2 years later.

As new areas enter the program, those no longer in the sample will be dropped. For areas retained in the program, changes in the geographic boundaries of metropolitan areas will be reflected in the year an area is surveyed by personal visit.

Most of the areas to be dropped from the area wage survey program will still be surveyed by BLS, but not as part of its own program. Each year the Bureau conducts about 100 locality wage surveys for the Employment Standards Administration of the U.S. Department of Labor.[14] Results from these surveys are used in administering the Service Contract Act, which sets minimum wages by occupation for employees of firms providing services to the Federal Government. ☐

—FOOTNOTES—

[1] The surveys include establishments in six broad industry divisions: manufacturing; transportation, communication, and other public utilities; wholesale trade; retail trade; finance, insurance, and real estate; and selected services. Major exclusions from the survey are construction, extractive industries, and government. Establishments employing 50 workers or more are included except in the 13 largest areas where the minimum establishment size is 100 workers in manufacturing; transportation, communication, and other public utilities; and retail trade.

[2] See, for example, *Area Wage Survey: New York, New York–New Jersey, Metropolitan Area, May 1985*, Bulletin 3030–32 (Bureau of Labor Statistics, September 1985). Summaries of each of the 70 surveyed areas are also reported in a single volume. See *Area Wage Surveys: Selected Metropolitan Areas, 1984*, Bulletin 3025–72 (Bureau of Labor Statistics, June 1985).

[3] See *Wage Differences Among Metropolitan Areas, 1984*, Summary 85–7 (Bureau of Labor Statistics, June 1985).

[4] See *Occupational Earnings in All Metropolitan Areas, July 1984*, Summary 85–4 (Bureau of Labor Statistics, May 1985).

[5] See, for example, John E. Buckley, "Wage differences among workers in the same job and establishment," *Monthly Labor Review*, March 1985, pp. 11–16. An annual report compares wage levels in the areas surveyed. A more detailed description of the area wage survey program, including a discussion of uses and limitations of survey findings, is in *BLS Handbook of Methods*, Vol. I, Bulletin 2134–1 (Bureau of Labor Statistics, December 1982), pp. 67–73.

[6] Test surveys including blue-collar jobs were conducted successfully in 1949 in six cities.

[7] The program also included surveys in two nonmetropolitan areas—Boise, Idaho, and Burlington, Vermont—located in States without metropolitan areas. In addition, several surveys not part of the regular area program were conducted under contract.

[8] See Virginia L. Ward, "Area sample changes in the area wage survey program," *Monthly Labor Review*, May 1975, pp. 49–50.

[9] The Chicago survey was limited to Cook County and the New York survey to the five boroughs until 1963.

[10] At times, changes have been made between census years.

[11] They are also contained in the *Statistical Reporter*, December 1979, pp. 33–45. For background information, see Federal Committee on Standard Metropolitan Statistical Areas, "Documents Relating to the Metropolitan Statistical Area Classification for the 1980's," *Statistical Reporter*, August 1980, pp. 335–84.

[12] MSA definitions generally do not change except after the decennial census. Each year, however, a few new MSA's may be announced, usually because of population growth.

[13] See Nathan Keyfitz, "Sampling with Probabilities Proportional to Size: Adjusting for Changes in the Probabilities," *Journal of the American Statistical Association*, No. 46, 1951, pp. 105–09.

BLS and Alice Hamilton: pioneers in industrial health

In the early years of the century,
BLS contracted for and published studies
of industrial health and safety;
its most active agent was Alice Hamilton,
'special investigator for industrial diseases'

William T. Moye

In September 1910, Alice Hamilton, chief medical examiner for the Illinois State Commission on Occupational Diseases, was in Brussels attending the International Congress on Occupational Diseases, at which the Belgian delegate dismissed U.S. activities in the field of industrial hygiene with the comment, "Ça n'existe pas [They do not exist]".[1] But that condition had already begun to change, and at the International Congress, Hamilton met Charles P. Neill, Commissioner of Labor, one of the persons primarily responsible for the recent surge in publicity on industrial poisons. Shortly thereafter, Hamilton accepted Neill's proposal that she undertake investigations for the Bureau of Labor, launching a decade of cooperation in which she studied diseases and hazards associated with the lead, explosives, pottery, and dye industries.

Early career

Hamilton was born in New York City in 1869, but was raised in Fort Wayne, IN, one of four sisters with a much younger brother. From her youth, she was determined to be useful. Indeed, at one point, she hoped to become a medical missionary in Persia.[2] In her activities, she was able to combine her medical work with humanitarian services.

Upon graduation from medical school at the University of Michigan in 1893, she worked at hospitals in Minneapolis and Boston before returning to Michigan for graduate work. Then she went to Europe for a year of study, followed by a year at Johns Hopkins. In 1897, she accepted a teaching position in Chicago and made the crucial decision to live at Hull House, a settlement house where she found "an intense and humane concern for people, especially for those who had small chance in this world."[3] There she found activities that married her research interests with social concerns.

During a typhoid epidemic in 1902, Hamilton surveyed homes in the Hull House district, capturing flies around open, undrained privies. When her tests confirmed the presence of the typhoid bacillus, she published the results of her research in the *Journal of the American Medical Association*, and along with other Hull House residents, urged the Chicago Board of Health to clean up the area.[4]

In 1908, Hamilton published her first article on industrial hygiene in *Charities and The Commons*.[5] She had to turn to Great Britain and Europe for information on the subject, "as there is so little available in our own country where we are still too much absorbed in the industrial battle to stop and take stock of the killed and wounded."[6] Later that year, Charles S. Deneen, governor of Illinois, appointed the Illinois Commission on Occupational Diseases—Hamilton and eight men. She served on the commission for about 2 years, resigning to accept the post of medical investigator for the Commission's Survey of Occupational Diseases.

Hamilton later wrote that her visit to European factories in 1911 had been an eye-opener. She had previously thought that U.S. factories provided better working conditions and that American workers enjoyed better health and, therefore, less industrial poisoning. However, after studying the sick-

---

William T. Moye, formerly a historian at the Bureau of Labor Statistics, is the command historian at the U.S. Army Laboratory Command.

ness records and dwellings of English and German workers, she realized that she had found "a far larger number of cases" during her Illinois surveys.[7]

According to Hamilton, when she entered the industrial-hygiene field, "You could have counted the published articles on industrial poisoning on the fingers of one hand." Employers eager to improve conditions could find but little advice from medical experts. Many supervisors simply relied on a large floating pool of foreigners and a high labor turnover rate to cut exposure time in hazardous trades.[8]

Efforts at the Bureau

Carroll D. Wright, first chief of the Bureau, had commissioned the first Federal report on industrial hygiene and published it in 1903. But the American awakening came later as part of the national push for social and economic reform known as the "Progressive Movement." Bureau activity in industrial hygiene was further spurred by the assumption of administrative functions under the Federal employees' compensation act of 1908. Neill placed special emphasis on industrial health and safety issues, and the Bureau participated in and encouraged research on these issues.

In 1909, the Bureau cooperated with the American Association for Labor Legislation in examining the effects of white phosphorus in the production of matches. The subsequent report, published by the Bureau in 1910, spurred the introduction of legislation banning phosphorus matches from interstate commerce and eventually resulted in passage of a law placing a heavy tax on such matches.[9]

In accepting Neill's proposal to associate with the Bureau of Labor, Hamilton assumed the title of "special investigator for industrial diseases," producing first "White-Lead Industry in the United States, With an Appendix on the Lead-Oxide Industry." She investigated 23 of the 25 U.S. factories known to manufacture white lead and discovered 358 specific cases of lead poisoning, 16 of them fatal, occurring between January 1910 and April 1911.[10] She then moved on to study problems of lead poisoning in potteries, tile works, and porcelain enameled sanitary ware, as well as in the painters' trade.

Royal Meeker, who succeeded Neill as Commissioner, lauded the results of Hamilton's work, "The studies of lead poisoning, made by the Federal Bureau of Labor Statistics, have induced some of the manufacturers of lead paints, pottery, tile, and storage batteries to eliminate or modify some of the most dangerous processes in their industries which subjected workers to needless hazards from lead poisoning."[11] Meeker wanted the Bureau to become a central clearinghouse, declaring, "This Bureau should be in a position to furnish at any time advice as to the best methods of preventing industrial accidents and occupational diseases."[12]

Hamilton's association with the Bureau continued, focusing first on problems in the lead industries, then the rubber industry, the printing trades, the manufacture of explosives, and the production of aniline dyes. She later wrote of the independence which Meeker allowed her and the support that he gave her: "I look back to my service under him with pleasure and gratitude. He gave me a free hand, but was always ready to help in any difficulty; he never edited my stuff and when nervous manufacturers asked to see it before publication, he would arrange a conference with them, call me in to defend my statements, and stand by me."[13]

Hamilton may have enjoyed the independence and freedom from red tape, but she suffered from a lack of reliable funding. She was employed by the Bureau on a contract, not a salary basis, selling each study for a negotiated amount. The Bureau itself suffered from limited appropriations, prompting Hamilton to write to her sister in 1914, "They are so poor they cannot make a contract with me for an investigation of rubber, but I mean to do it anyway and trust to their making it in July, the new fiscal year."[14] Preferring the freedom and variety afforded by her association with the Bureau, she turned down job offers carrying larger salaries but with more restrictions. However, she did supplement her income by writing articles for *The Survey*.[15]

Early on, Hamilton developed her techniques of "shoe-leather epidemiology." Of her experiences in Illinois, she said, "No one method of investigation can be adopted. One must simply grope and catch at anything which offers the least help." She noted that England and Germany kept official records of workers' sicknesses. By contrast, "In Illinois, one must simply grope again, and one must carefully check up and control every bit of information one gets."[16]

Hamilton's biographer wrote of her procedures: thorough investigation of factories, correlation of illness with specific industrial processes, and compilation of medically diagnosed cases of poisoning. Before heading to the field, she learned the technical side of an industry. Then, she would observe all processes, carefully check hospital and dispensary records, and talk to the workers in their homes and union halls—and saloons, if necessary.[17]

Hamilton wrote her sister of "the risky things one has to do" as part of an investigation of Arizona copper mines: "climb steep ladders down into black holes, or scramble up through low caves on one's hands and knees, or pick one's way over rails laid across a deep dump, or be hauled up a rock that has no foothold." She was 50 years old at the time.[18]

She adamantly defended her work. When one of her early studies was attacked by a company doctor who was also a member of the State board of health as "a striking example of exaggeration, either a false and apparently a malicious and slanderous report, or an erroneous one," Hamilton wrote her superior at the Bureau of her distress. She supported her findings, naming sources and doctors she had interviewed and listing the establishments she had visited.[19]

She readily adopted the Bureau's tradition of objectivity as the best way to ensure the good will of the business community—and, therefore, entrance to the plants, as no Federal law granted entry and businessmen gave access at their own discretion. (She later wrote that she could remember only two large factories refusing her entrance.) She made it a point to discuss her observations and criticisms with plant managers in private consultations.

Some plant managers did try to cover up poor conditions, for example, one lead works in the Middle West. Hamilton described that company's village as "the most depressing industrial community I have ever seen." One woman informed her, "We all knew you was coming. They've been cleaning up for you something fierce. Why, in the room where my husband works, they tore out the ceiling because they couldn't cover up the red lead. And a doctor came and looked at all the men and them that's got lead, forty of them, has got to keep to home the day you're there." When Hamilton told the management of her findings, the company admitted the fraud, showed her the doctor's report, and promised permanent improvements, including regular medical examinations for all employees.[20]

World War I brought new concerns to the fore, and Hamilton surveyed conditions in such war-related industries as munitions and airplace manufacturing. She also studied aniline and other coal-tar dyes, in which U.S. manufacturers were replacing the German products previously imported.[21]

In a 1917 article in *The Survey,* she discussed "a new form of industrial poisoning from the manufacture of airplane wings, which, so it appears, has caused a good deal of trouble in England." The BLS asked her to investigate the kinds of "dope" used to treat the wings of planes manufactured in the United States, and the conditions under which it was applied. She toured 18 factories and reported, "on the whole, my findings were reassuring."[22]

Because of the secrecy surrounding munitions plants, Hamilton herself had to discover where the plants were located and what they produced. For example, her search for picric acid led her to the marshes of New Jersey where she followed the chemical's characteristic fumes to their source, or she would spot the orange- and yellow-stained men, known as "canaries," who would then lead her to the site.[23]

The Bureau participated in joint projects with agencies in the War Labor Administration of the Department of Labor. For the Working Conditions Service, Hamilton chaired a committee of experts studying health problems arising from industrial poisons. The Bureau also worked with the Woman in Industry Service, teaming with the Public Health Service. Both Meeker and Hamilton participated in an investigation of conditions at Niagara Falls, where plants wanted to work women at night to speed deliveries to the military and other war industries, action prohibited by New York State labor law.

Hamilton worked with the Committee on Industrial Diseases, Poisons, and Explosives organized by the Committee on Labor of the Advisory Commission of the Council of National Defense. She also designed studies for the Committee on Industrial Poisons of the National Research Council's Division of Medicine and Related Services.

She was appalled by "the sight of men sickening and dying in the effort to produce something that would wound or kill other men like themselves."[24] However, she chose not to protest the war as conspicuously as she might otherwise so she could keep her job with the Bureau where she could continue to expose hazards and establish protective standards, characterizing her investigations as "a patriotic duty, as a piece of real war work and yet not the destructive side of war but the saving of life."[25]

After the war, Hamilton wrote, "England and France, facing an emergency infinitely greater than ours, took thought to protect their munitions workers, but we did not."[26] As one writer has said, Hamilton cast her lot with those institutions primarily concerned with "workers' welfare, not industrial productivity."[27]

The later years

The Bureau gradually lost control of Federal occupational health programs to the better financed and equipped Public Health Service. Hamilton, so active during the war years, hesitated to return to the peace-time Bureau, saying, "it will be too depressing to go back to general oblivion again."[28]

Fortuitously, during her wartime work, she had met David L. Edsall, dean of the Harvard Medical School, who had launched the first degree program in the United States in industrial hygiene. In 1919, Edsall offered Hamilton an appointment to teach industrial medicine, and she became the first woman on the Harvard faculty.

Edsall wrote the president of Harvard that Hamilton's studies were "unquestionably both more extensive and of finer quality than those of anyone else who has done work of this kind in this country."[29] Hamilton commented, "going to Harvard is very grand. If one could wear it as a decoration, like the Order of the Garter, I would love it."[30]

She worked only part time at Harvard, but she was so active on so many fronts that one writer labeled her "the Tinker Bell of industrial medicine."[31] She contributed articles to the *Journal of Industrial Hygiene*, edited at Harvard. In 1925, she published *Industrial Hygiene in the United States*, the first American textbook in the field, following it in 1934 with *Industrial Toxicology*. Also during that period, several lead companies, at Hamilton's initiative, agreed to fund a 3-year study of lead poisoning to be headed by a Harvard physiologist.[32]

Hamilton helped stimulate Federal action leading to two conferences, one on tetra-ethyl lead in 1925 and the other on radium in 1928. She praised the "informal and extra-legal method" of investigation, conference, and agreement between manufacturers and State and Federal health officials as "the only way a quick and effective reform can be brought about in several different States simultaneously." However, she warned, the method worked only on "a new striking danger which lends itself to newspaper publicity"—not old familiar dangers or newer, less spectacular poisons.[33]

Therefore, she continued to urge passage of adequate compensation laws as "the best preventive measure for industrial diseases," pointing to the powerful influence of insurance companies on employers with excessive numbers of claims because of poor conditions.[34]

Upon retirement from Harvard in 1935, Hamilton returned to the Department of Labor—whose chief was Frances Perkins, a fellow member of the social reform network. In accepting the part-time job as medical consultant to the Division of Labor Standards, she rejected a full-time offer from the BLS rival, the Public Health Service.

As consultant, she conducted surveys, offered advice, attended conferences, testified at hearings, and brought neglected problems to the Department's attention. Her most important work during the period involved a study of poisons in the manufacture of viscose rayon. Years earlier, she had discovered cases of carbon disulphide poisoning arising from the process for vulcanizing rubber. Yet, despite her efforts and considerable European literature on the subject, there had been no systematic investigation in the United States. In the face of industry opposition, Hamilton conducted a survey in Pennsylvania and extended the work to cover nine other States, resulting in *Occupational Poisoning in the Viscose Rayon Industry*, published by the Division of Labor Standards in 1940.[35]

Alice Hamilton died at her home in Hadlyme, Connecticut, September 22, 1970, a few months before the Occupational Safety and Health Act was signed into law. The previous year, on her 100th birthday, President Richard Nixon had praised her "lasting contributions to the well being of our people and of men and women everywhere."[36] ☐

Conference Papers

The following excerpts, closely related to the work of BLS, are adapted from papers presented at the Thirty-Eighth Annual Meeting of the Industrial Relations Research Association, December 1985, in New York.

The full text of the papers appears in the copyrighted IRRA publication, *Proceedings of the Thirty-Eighth Annual Meetings,* available from IRRA, University of Wisconsin, Social Science Building, Madison, WI 53706.

Labor-market data: supplementary sources

SANFORD M. JACOBY AND DANIEL J.B. MITCHELL

In the past, private organizations and State government agencies attempted to fill some of the statistical gaps left by the Bureau of Labor Statistics. Current evidence suggests that the same tendency still exists: if there is a market for data, some organization often steps in to provide them, either for reasons of public relations, or as a direct item for sale. In addition, State statistical agencies will provide information felt to be useful within their jurisdictions.

To illustrate these sources—and their pitfalls—two areas are discussed below: salary intention surveys and State industrial relations data.[1]

Salary intention surveys

Although it is possible to collect data on expectations and intentions (as the Commerce Department does with regard to plant and equipment expenditures), BLS has not collected data on *planned* pay adjustments. Some information is of potential use to pay setters and to economic forecasters, and some management consulting firms do survey such information.

As an example, data are collected by Hewitt Associates on pay adjustments planned and under way for salaried employees. We compared the Hewitt figures with realized wage adjustments for white-collar workers taken from the Employment Cost Index. It appears that surveyed personnel managers at first underestimated the degree of wage disinflation occurring in the early 1980's, but then stabilized their expectations in line with actual results. Thus, the Hewitt data provide insight into the shift of wage norms that developed during the economic downturn of 1980–82.

Unfortunately, use of salary intention surveys is hindered by the misunderstanding common among personnel managers concerning the cost of "merit" increases. Particularly among nonunion employers, there is often a confusion between the gross and net effects of merit pay awards. In a steady-state situation, a properly operated merit system (in which across-the-board adjustments are segregated from merit awards) should not raise average pay.[2] Yet respondents to the Hewitt and other surveys seem to include gross merit awards in their estimates, thus biasing up the figures by roughly 1 to 2 percent. These upward-biased estimates are then cited, giving a misleading indication of likely wage trends.[3] The merit problem illustrates the more general methodological weakness sometimes associated with private data suppliers.

State industrial relations data

Although some State labor statistics agencies predate the BLS, they have had a much less visible role collecting data in modern times. Often, data available from State agencies are derived from BLS or Census series. But in some States, the agency collects industrial relations data on its own. For example, the California Department of Industrial Relations puts out data on union wage settlements and union membership by industry and region.

It is unlikely, however, that State agencies will quickly fill gaps left by the reduction of BLS data collection. For example, eight States were reported to have issued union membership data during 1984, according to the *Statistical Reference Index*. But closer inspection reveals that all but three (California, South Carolina, and Wyoming) are still reproducing the now-discontinued BLS series from 1978 or 1980. States which collected their own membership prior to the BLS discontinuation continue to do so; the others have not been motivated to undertake the effort.

TO THE EXTENT that a market or a public relations value is perceived for collecting labor market data, private sector organizations often undertake the task. However, general availability of such data for research purposes can be a problem. And problems of methodology (sampling, precise

---

Sanford M. Jacoby is an associate professor, Graduate School of Management, University of California at Los Angeles, and Daniel J.B. Mitchell is Director, Institute of Industrial Relations, UCLA. The full title of their IRRA paper is, "Alternative Sources of Labor Market Data."

definitions, technical explanations) are less likely to concern private suppliers than BLS. Private organizations have less authority than a government agency in requesting cooperation with surveys; potential respondents may have concerns about confidentiality and the use to which data will be put; and the users themselves may be less sophisticated than statistical technicians about methodological issues. These factors suggest that private collection—while playing a useful role in data provision—is really a complement to, rather than a substitute for, Federally collected data.

State government statistical bureaus do have a level of authority not found in the private sector. But they have tended to become reliant on breakdowns from Federal data sources for much of their output. And the statistical output which State agencies produce is largely applicable only within their borders. ☐

[1] References to non-BLS data sources can be found in Margaret A. Chaplan, *Labor Statistics: The BLS and Beyond* (Champaign, University of Illinois, 1984), Reprint 322; and Katherine I. Bagin and Kevin P. Barry, *Unexpected Sources of Information in Industrial Relations: A Current Awareness Approach* (Princeton, NJ, Princeton University, Industrial Relations Section, 1984).

[2] Imagine a formal progression plan with a series of defined merit steps. As long as the proportion of employees at each step is constant, the average wage will not change. In the steady state, the number of employees retiring from the top will be offset by those entering from the bottom. Thus, although existing workers may be receiving large merit increases (depending on the gap between steps), the average wage will remain constant. Confusion over this issue is rampant because managers are often given "merit budgets" as a control device to prevent them from finding "too many" employees to be especially meritorious. These merit budgets often are based on gross cost or may include what amounts to across-the-board money designed to raise the average wage. See Arnold R. Weber and Daniel J.B. Mitchell, *The Pay Board's Progress: Wage Controls in Phase II* (Washington, The Brookings Institution, 1978), pp. 89–93.

[3] Hewitt's questionnaire asks respondents to calculate a salary structure increase based on the movement of the midpoint of salary ranges and an average base salary increase. The former is essentially a rate range adjustment and should be free of any merit system "taint." The latter, defined as the increase in the average wage per employee, ought to include only the *net* cost of merit (which in the steady state should be zero). Yet, it is typically 1 to 2 percent higher than the former, suggesting respondents are using a gross cost of merit in their calculations. (When Hewitt asked its respondents in late 1984 whether they were following the precise instructions of the questionnaire, 70 percent said "yes," suggesting that the problem is based on inadvertent misunderstanding of the impact of merit pay.) Unfortunately, it is the base salary increase (and similar estimates from other surveys) that tends to be reported. (See, for example, Audrey Freedman and others, *Labor Outlook 1985* (New York, The Conference Board, 1984), p. 9.

Airline deregulation and labor relations

WILLIAM J. CURTIN

Over the past 6 years, the process of deregulation has placed great stress on the system of industrial relations in the airline industry. Numerous commentators have described the scenario by which deregulation has led to an increase in competition in the product market by encouraging new entrants and by allowing existing carriers to expand their routes. Some of the new entrants have successfully operated on a nonunion basis and, as such, have enjoyed significant cost advantages because of lower wages, lower benefit costs, and less stringent work rules.[1] This, in turn, has created industrial relations pressure on established carriers with unionized operations to seek significant concessions from unions in order to compete with the nonunion entrants.

Professor John T. Dunlop has properly asserted that the industrial relations problems created by deregulation have been exacerbated by the fact that, prior to deregulation, inadequate consideration was given to the question of how deregulation would impact the relevant labor markets and the process of collective bargaining.[2] Initially, the theoretical case for deregulation focused on the need for competition in the product market. Little attention was paid to the fact that collective bargaining in the airline industry traditionally operated as a form of labor market regulation that allowed unions to capture a portion of the monopoly profits generated by regulation of the product market. As a consequence, the disequilibrium that followed the withdrawal of product market regulation was not anticipated.

In examining the impact of deregulation on the airline industry, it is important to remember that much of the process of deregulation occurred during one of the worst economic recessions in recent memory. This economic downturn undoubtedly compounded the industrial relations problems.

Deregulation's early impact

Early in the process of deregulation, the disequilibrium described above presented a severe threat to the traditional economic power of certain airline unions. Additionally, there were events that caused some concern over the continuing viability of the process of collective bargaining under the Railway Labor Act.

The experience at Continental Airlines reinforced these perceptions. On September 24, 1983, Continental, the eighth largest passenger airline in the United States, filed a petition for bankruptcy under Chapter 11 of the Bankruptcy Code. Pursuant to its perceived powers under Chapter 11, Continental unilaterally implemented drastic changes in wages, benefits, and work rules.[3] In response, the Air Line Pilots Association, the International Association of Machinists, and the Union of Flight Attendants went on strike. Although these strikes dragged on for many months, they did not halt Continental's operations and they eventually were discontinued without a restoration of prepetition wages and benefits.

A surprising aspect of the Continental experience was that significant reductions in wages and benefits were imposed unilaterally and outside the traditional process of collective bargaining. To support the assertion that the Continental case was perceived as a threat to the entire process of collec-

William J. Curtin is a senior partner in the law firm of Morgan, Lewis & Bockius, Washington, DC. The full title of his IRRA paper is "Airline Labor Relations Under Deregulation."

tive bargaining, one only need recall the vigor with which both National Labor Relations Act and Railway Labor Act unions sought Congressional action to amend the Bankruptcy Code to prevent repetitions of the Continental initiative.[4]

Moreover, union setbacks were not limited to bankruptcy context. During late 1983, the Allied Pilots Association, as representative of American Airlines' pilots, agreed to a two-tier wage scale. This scale reduced pay for new hires by nearly 50 percent.[5] In addition, the scales at American did not merge at any set time in the future. New hires remained permanently on a separate and lower scale.[6] In the wake of the American agreement, Eastern, Delta, Western, Republic, and Pan Am also sought concessionary packages.

More recent developments

Recently there have been significant developments in airline labor relations that may indicate a trend toward stabilization. First, it appears that Chapter 11 no longer exists as an easy method to reduce labor costs without undertaking the rigors of concessionary bargaining. In 1984, Congress amended the Bankruptcy Code by adding section 1113, regulating the rejection of collective bargaining agreements.[7] In a review of section 1113, two points are most significant. First, as a prerequisite to the rejection of any collective bargaining agreement, an employer must engage in collective bargaining with its union(s). The new statute specifically requires that an employer seeking rejection must (1) make a proposal to the union; (2) provide the union with information to evaluate that proposal; and (3) engage in good-faith negotiations prior to rejection.[8] Second, if this bargaining is not successful, an employer must seek court approval before unilaterally changing the contract.[9] In short, the type of swift, unilateral action undertaken by Continental Airlines is now impossible.

In addition to these changes in the applicable legal framework, there have been changes in the labor market, particularly for pilots, that would make it very difficult for another carrier to duplicate the coup accomplished by Continental. One of the keys to Continental's success in the face of the Air Line Pilots Association's strike was its ability to hire outside replacements.[10] Today, many airlines are experiencing a shortage of qualified pilot applicants. Indeed, the market is so tight that some carriers have been forced to reduce qualifications and increase pay.[11]

If a carrier were to attempt to reject its collective bargaining agreement in this type of labor market, the Air Line Pilots Association probably would be able to mount a more effective strike effort. Moreover, the recent experience at Wheeling-Pittsburgh[12] suggests that the rejection of a collective bargaining agreement under the Bankruptcy Code may not result in tremendous cost savings if a union is able to conduct an effective strike in the face of that rejection. Therefore, for both legal and economic reasons, it is unlikely that another carrier would be able to duplicate Continental's experience.

Other recent developments in airline bargaining indicate that airline unions may be regaining a measure of their former vigor and that it may become more difficult for carriers to exact cost-saving concessions. For example, since late 1984, the Air Line Pilots Association has undergone something of a transformation. Most significant in this regard is that the international union has attempted to assert greater control over the substance of collective bargaining agreements negotiated by Master Executive Councils, the subordinate Air Line Pilots Association groups existing at each carrier. To this end, the international union has adopted guidelines for crisis or concessionary bargaining.[13] The Association also amended its constitution to give its president the right to approve all pilot contracts before they take effect and to put dissident locals into trusteeship. Finally, the Association has undertaken a program to improve communications with members. During the recent strike at United Airlines, the Air Line Pilots Association engaged in a series of nationwide "teleconferences" to keep pilots informed about the latest developments and to secure support for the strike.

Some time ago, Professor John Dunlop predicted that the significant disruptions in airline labor relations caused by deregulation and concessionary bargaining would be concentrated in a transitional period.[14] The foregoing discussion indicates that the airline industry may be approaching the end of this transitional period and entering a new stage of relative stability. □

[1] See *In re: Continental Airlines Corp.*, No. 83-04019-H2-5, slip. op. at 4 (Bankr. S.D. Tex. Aug. 17, 1984). In addition, some new entrants have cost advantages that are not labor-related, for example, lower overhead due to their ability to use secondary airports. See address by John T. Dunlop, National Academy of Sciences, Transportation Research Board (Jan. 14, 1985) (hereinafter "Dunlop Speech").

[2] See "Dunlop Speech."

[3] For example, Continental decreased average earnings for pilot captains from $90,000 per year to $42,000 per year. Similarly, "hard hours" for captains were increased from 52 to 68 per month. See *In re: Continental Airlines Corp.*, Findings of Fact 30–38.

The 1984 postal arbitration: issues surrounding the award

J. JOSEPH LOEWENBERG

The 1984 interest arbitration was the first time that the United States Postal Service (USPS) and its two largest unions, the American Postal Workers Union and the National Association of Letter Carriers, implemented the legislated impasse procedure of the Postal Reorganization Act of 1970 to resolve all economic issues raised in bargaining. As such, it represented a significant development in postal labor relations and resulted in an award for more than 500,000 employees, the largest number of workers involved in a single arbitration in the United States. It also raised questions about standards to be employed in wage-setting and in interest arbitration.

The 1984 negotiations

The 1984 postal negotiations were the first postal labor talks since the air traffic controllers' strike of 1981. The tone for the negotiations was set by a policy statement issued by the Board of Governors of USPS 2 weeks before the initial bargaining meeting which found that postal workers' compensation exceeded that of comparable private-sector employees and which therefore directed USPS management "to seek correction of this situation."[1] The mandate of the Board was reflected in management's economic proposals which included a two-tier wage structure, with the scale for new hires 33 percent below the current base.

The unions' Joint Bargaining Committee (JBC) believed that the USPS proposal was regressive and unwarranted by the economic success of USPS. Postal volume had continued to climb in spite of rate hikes and of doomsayers who had predicted a decline in hard mail copy. Annual productivity had also increased beyond that in the private sector in 7 of the last 10 years. USPS had accumulated more than $1.5 billion in surplus in 3 successive years, even though congressional subsidies had ended. Moreover, the unions claimed that employees had received an overly modest economic settlement in the 1981 agreement. JBC wanted significant improvements in wages and benefits.

Negotiations were unsuccessful. Impasse procedures were initiated. Another attempt at negotiations proved no more successful than the earlier one, leading the parties to mandated binding arbitration.

Interest arbitration

The statutory arbitration format is a three-member panel, with each party choosing one member and those two selecting a third; if the two are unable to agree, the director of the Federal Mediation and Conciliation Service designates the impartial neutral. The tripartite panel has 45 days in which to issue its award. In 1984, the statutory scheme was complicated by the presence of a joint bargaining team of two unions and by a time frame much shorter than the statute envisioned. The parties eventually agreed on a five-member panel: each union would nominate a member to the panel; USPS would nominate two members to balance the union representation; and one impartial chairman would be selected. Each representative arbitrator would cast a half vote; the chairman would be entitled to a full vote. The impartial chairman was Clark Kerr, an arbitrator and former chancellor of the University of California at Berkeley. The deadline for the arbitration award according to the statutory timetable was December 25. The hearings began December 11 and concluded on December 19.

The central question addressed by the parties during the arbitration hearings was the interpretation of Section 1003 of the Postal Reorganization Act of 1970:

> It shall be the policy of the Postal Service to maintain compensation and benefits for all officers and employees on a standard of comparability to the compensation and benefits paid for comparable levels of work in the private sector of the economy.

To demonstrate that postal employees were paid a premium over comparable private-sector employees, USPS presented expert witnesses to testify on econometric studies, job evaluation studies, occupational wage surveys, and package industry wage surveys. JBC denied that the statutory mandate should be the sole criterion guiding the arbitrators, but was willing to present evidence to counter that presented by USPS.

The key witnesses were Michael Wachter for USPS and Joel Popkin for JBC. Their testimony centered on the validity of their respective econometric studies about the existence and size of a premium of postal wages over private sector wages and about the applicability or utility of their findings to collective bargaining.[2] The importance attached to these witnesses and an unusual departure from typical arbitration hearing procedure was, following their testimony, a joint seminar before the arbitration panel to allow Wachter and Popkin to discuss their studies, point out areas of agreement, and challenge each other on areas of disagreement.

Wachter asked the research question, "What wage would a postal employee get in alternative sources of employment?" and concluded that USPS paid a premium of 19.8 percent over the private sector. If only the wages of unionized workers in the private sector were used as a comparison, the wage premium for postal employees would still be 12.2 percent. Wachter validated his results by looking at the large number of applicants for postal jobs, low quit rates, lack of unemployment, and a comparison of wages of new hires as postal mail handlers and material handlers in private industry.

Popkin noted that 20.5 percent of represented employees were nonwhite and 27 percent were women. He hypothesized that private industry discriminated in setting wages,

---

J. Joseph Loewenberg is professor of industrial relations, Temple University. The title of his full IRRA paper is "What's 13 Billion Among Friends? The 1984 Postal Arbitration."

particularly against female and nonwhite employees performing work similar to that of white men. Given that USPS was not a discriminatory employer, the white-male wage comparison was the appropriate one for determining comparability. The addition of race and sex variables in the regression analysis accounted for the major portion of postal-private sector wage differentials. In addition, Popkin included variables for firm size, proportion of industry unionized, and tenure in current job, all of which had been shown to affect wage levels. He found no statistical significance between the wages of white men in USPS and those of white men comparably situated in the private sector.

The arbitration award provided for a 3-year agreement retroactive to July 20, 1984. The award increased the salaries in the current wage schedule by 2.7 percent annually for incumbent employees. New employees in the first seven grades would start at steps below those currently in the wage schedule: three new steps for grades 1–3 and two new steps for grades 4–7. The time for a newly hired employee to reach step 1 of the 1981-84 wage scale would be 272 weeks for grades 1–3, 184 weeks for grade 4, and 140 weeks for grades 5–7. To reach the top of scale would require from 13 years in grades 1–3 to 10.5 years in grades 5–7. The award added a new step at the top of the grade 8 wage scale and two new steps at the top of the wage scales for grades 9 and 10. The COLA formula and times of computation were maintained. COLA accumulated under the 1981-84 agreement would be rolled into the basic salary schedule in October 1987, except that employees eligible for retirement by 1990 could elect an earlier roll-in. Martin Luther King Day was added as a holiday beginning in 1986. The uniform allowance was increased 10 percent. No change was awarded in leave, benefit plans, and premium pay provisions. It was estimated that the award would add approximately $4 billion in postal costs.[3] Kerr explained the basis for the award:

> This award reflects a policy of "moderate restraint" . . . . This award interprets moderate restraint as a slowing of wage increases, as against the private sector, by 1 percent a year or for 3 percent in total over the life of this agreement.[4]

Issues raised

The 1984 postal arbitration raised fundamental questions about the interpretation of statutory provisions for wage-setting in USPS, the relative roles of these provisions and collective bargaining, and the criteria to be used by arbitrators. The issues were identified and discussed; all were not answered clearly.

Several aspects of Section 1003 of the Postal Reorganization Act may be ambiguous. First, the provision calls for USPS "to maintain" comparable compensation and benefits. Does this suggest a minimum, a general guide, or an absolute standard for setting compensation? As might be expected, JBC argued the first approach, while USPS adopted the last one. Second, what is the base period for comparisons? Wachter advocated 1969 because that was the last year before postal reorganization was discussed seriously by the Congress. Counsel for USPS used 1970 on the ground that the Congress awarded postal employees wage raises following the end of the 1970 strike to establish comparable rates. The unions adopted 1971 since that was the first time the parties bargained collectively and interpreted freely the meaning of the statutory language. The choice of a base period for comparisons affects the results, especially because postal wages rose significantly between 1969 and 1971. Third, how does one define "comparable levels of work in the private sector of the economy?" The USPS utilized a broad, all-inclusive definition to measure comparability. The unions preferred a more limited definition for comparative purposes.

Even if these thorny issues regarding interpretation of Section 1003 could be resolved, the question remains of the significance of the statutory standards for collective bargaining. Congress granted postal employees the right to bargain collectively on wages, hours, and conditions of employment. If wages were determined by an agreed-upon definition of comparability, what would remain for the negotiation of wages? Collective bargaining would then be subordinated to the interpretation of Section 1003 promoted by USPS at the arbitration hearings.

For the arbitrators, the issue was further compounded by that of appropriate arbitral standards. The USPS contended that comparability was the sole standard before the panel. The unions argued for a more flexible approach, suggesting that the arbitrators refer to past collective bargaining settlements between the parties as a guide in their decision. The award also raised additional questions. If postal employees had gained a premium of the amount suggested by Wachter, what reason could there have been to award incumbent employees any wage increase, let alone one more generous than the parties had negotiated in their prior agreement? How are the parties to interpret these results in future negotiations? And is it simply coincidental that the cost of the award was $4 billion, the same as that of the 1981–84 agreement and the amount USPS projected in its filings with the Postal Rate Commission earlier in 1984?

It is easier to raise questions than to fashion interest arbitration awards. Issuing an interest award 5 days after the end of hearings is an accomplishment. The Kerr panel indicated some directions, provided solace to the parties, and carefully avoided direct answers to fundamental questions. While neither side achieved all it had sought, each could live with the result. Perhaps no more should be expected from interest arbitration. □

Union membership trends: a study of the Garment Workers

SHULAMIT KAHN

Aggregation obscures. When union growth and contraction are studied on the national level, many systematic influences on union growth within particular industries are lost. This is both because union membership's sensitivity to these influences differs widely among industries, and because changes in the influencing factors are often distributed very unevenly among industries.

One factor that will be particularly difficult to consider on a nationally aggregated level is imports. Imports have been blamed for the last decade's sharply decreasing unionization rate. To evaluate this assertion empirically, it is necessary to study the impact of imports in particular industries rather than the impact of the overall U.S. balance of trade on the national unionization rate. A related reason to study union changes within specific industries is to separate the two kinds of factors that influence aggregate union membership: changes in the size of heavily unionized industries versus the strength of the unions within the industries.

This paper studies changes in the size of one specific industry and union, the International Ladies' Garment Workers' Union (ILGWU). The ILGWU is a mature union both with regard to age and waning strength, and is located in an industry undergoing many changes that have weakened the union's position. Membership in the ILGWU has decreased sharply since 1970, both absolutely and as a percentage of industry employment.

Modeling membership in the ILGWU

Econometric studies of aggregate union membership began with Orley Ashenfelter and John H. Pencavel's seminal 1969 paper,[1] which considered the impact of both economic and political factors. Numerous subsequent studies attempt to test this model and to increase explanatory power by changing both the dependent and independent variables. Do these aggregate models explain ILGWU membership adequately?

Equation 1 of table 1 replicates for the ILGWU a model similar to Ashenfelter and Pencavel's, but incorporates some modifications from the later literature.[2] The period covered is limited to post-1950, because of data availability.[3] In equation 1, the rate of change in ILGWU membership is modeled as a function of: a) the rate of change in the Consumer Price Index (PCCPI); b) separate variables for the percentage increases (UP) and decreases (UN) in the nondurable manufacturing unemployment rate[4]; c) the density or saturation of the industry (lagged 1 year),[5] measured as the inverse of the level of union density, or [ILGWU membership/employment in the women's apparel industry]$^{-1}$; and, d) a political variable, DEMOC, the percent of Democrats in the House of Representatives.

Because equation 1 exhibits substantial serial correlation, the Cochrane-Orcutt technique was used to correct for first-order autocorrelation.[6] The reestimated version appears as equation 2.

Neither model explains a large proportion of the changes in ILGWU membership, with adjusted R^2's of 30 percent and 43 percent, respectively. In contrast, the Ashenfelter-Pencavel model and other subsequent studies of aggregate union growth explained as much as 75 percent of the 20th century variation in U.S. union membership. Possible reasons for the relative success of the latter models are presented in the paper from which this discussion is excerpted.

We can explain far more of the growth in ILGWU membership by including other industry-specific factors in the equation. To this end, the results of several alternative models of

[3] Results pertain to the period 1951–81.

NOTE: t statistics in parentheses.

Shulamit Kahn is assistant professor of economics at the University of California, Irvine. Her full IRRA paper is entitled, "Trends in Union Membership in the Postwar Period: The Case of the ILGWU."

ILGWU union membership also are presented in table 1. There are two versions of the dependent variable: the first is the percentage change in union membership (%CMEM), which is used by most aggregate time series models; the alternative is the change in the percentage of all (production) workers in the female garment industry who are unionized (C%MEM). The latter is conceptually a better measure of the unionization of the industry, because it focuses on the percentage of the industry unionized. However, movements in this variable are generally caused by short-term cyclical shocks in the denominator, the employment level, which varies more than union membership. Therefore, because C%MEM may simply be measuring movements in employment, I concentrate on the alternative dependent variable, %CMEM. The models reported also differ in the explanatory variables included. (All of the alternative versions correct for first-order serial correlation.)

Of central interest here are the explanatory variables that do not appear in studies of aggregate time series union growth and are expected to affect the elasticity of demand for labor in the ladies' garment industry. The first of these is the level of imports, which is claimed to affect unionization adversely. Imports are measured as the ratio of clothing imports to the total value added in the U.S. apparel manufacturing industry, lagged 1 year to avoid simultaneity problems. All of the model specifications corroborate the widely held perception that foreign competition has substantially weakened the ILGWU. The coefficient on IMPORTS is large and statistically significant in all equations. Indeed, if *only* imports are included in the regression, 25 percent of the variance in the change in union membership is explained.

A second factor that can weaken unions is the substitutability of capital for labor. There is no straightforward way to measure this substitutability. However, the capital/labor ratio may indicate future opportunities for substitution, because if the capital/labor ratio is already high, future capital substitutability is not a substantial threat. Thus, the capital/labor ratio is expected to be positively correlated with union membership. The variable used to measure the capital/labor ratio, K/L, is the lagged change in the capital stock of the industry divided by the employment level.[7] The expected positive relationship is confirmed by all model specifications.

A third factor that should affect the elasticity of demand for labor, and thereby have an influence on union strength, is the ratio of labor costs to total costs. Unions have more strength when the demand for their labor is inelastic, and a smaller ratio of labor costs to total costs is one factor that leads to inelastic demand for labor. Therefore, we expect a negative relationship between the (lagged) ratio of labor costs to total cost (LC/TC) and union membership. However, the empirical results measure a significant positive relationship. One possible explanation for this result is that firms may hire more workers when they anticipate that union strength may be growing, in order to dilute union gains.[8] Alternatively, the LC/TC variable may be measuring an unemployment effect in the apparel industry that is not already being captured by the less specific nondurable manufacturing unemployment rate variables.

Equation 3 also includes all variables in the Ashenfelter-Pencavel model. As in the simpler specifications, a positive increase in unemployment rates consistently causes ILGWU membership to fall, while decreases are never significant. Increases in unemployment rates deter unionization both because workers are concerned about being laid off in the downturn and because they realize that the chances of finding a job if laid off are lower when unemployment rates are higher.

The sign on the lagged saturation (or density) variable used by Ashenfelter-Pencavel, defined above, is positive as expected, but not significant at any conventional level. Both because of the insignificant result and because there are theoretical problems in using and interpreting this variable, which is basically a lagged version of the dependent variable (percent unionized), it was not included in subsequent specifications. The Democratic percentage of the House has no effect on ILGWU membership, so it too was dropped from further specifications.

As in many of the aggregate time series studies, a measure of actual wage levels (in women's outerwear) was included. The variable PCNW denotes percentage change in the nominal wage in the industry, while PCRW is the percent change in the real wage. In specifications 3 and 4, nominal wages and prices are included in the specification separately, allowing nominal and real wages to have differing effects. In specifications 5 and 6, only real wages appear, thus constraining nominal wages to have no separate effect. This constraint cannot be rejected, that is, real wages are the only wage variable that significantly affects ILGWU size.

Both definitions of wages are lagged to avoid measuring the direct effect of unionization on workers' wages. Rising prices erode workers' earning power and are expected to create incentives to unionize; falling wages in the apparel industry may have the same effect. However, in a heavily unionized industry, falling wages may indicate that the union has not been successful in achieving its goals, and inhibit further unionization. In fact, results in specifications 3 through 6 weakly indicate that last year's wages may be negatively related to union membership change, while wages 2 years ago may be positively related. (Recall that with the degrees of freedom in the model, for .95 significance the t statistic must be larger than 2.1.)

The percentage change in industry employment, PCEMP, has a different interpretation and expected sign with the two different dependent variables. When %CMEM, the percentage change in union membership, is the dependent variable, the change in employment measures the increase in potential membership. It is expected to have a positive sign, yet is insignificantly different from zero in specifications 1 through 5. Other specifications not reported in table 1 also included a 1-year lagged percentage change in industry employment, or $\text{PCEMP}_{(-1)}$; this coefficient was also indistinguishable from zero at any conventional significance level. These results suggest that during the postwar period, increases and subsequent decreases of ILGWU membership were not affected by changes in the available pool of unionizable workers. People entering the industry did not immediately enter the union, and new plants were not immediately organized. Instead, the size of the membership depended completely on prospects for the union's bargaining strength.

In equation 6, the dependent varible is C%MEM, the change in the percentage of the industry unionized. This equation includes the independent variable PCEMP, percentage change in industry employment, to capture changes in the denominator of C%MEM caused by short-term fluctuations in the employment level. The sign, as expected, is negative—that is, higher industry employment increases the denominator of the dependent variable. ☐

Labor market segmentation in Japan: how rigid is it?

KOJI TAIRA

In Japan, segmentation largely refers to two sets of firms, large and small, rather than to two sets of jobs, primary and secondary, as in the United States. The size of a firm in Japan is an unusually powerful factor that makes firms and employees behave differently. These differences are observable in all aspects of management, technology, and human resource utilization. Large firms are characterized by elaborate rules, procedures, and processes of "internal labor markets." They can therefore be considered constituting an "internal labor-market sector." This syndrome is entrenched in firms large enough to employ 1,000 or more workers; however it may begin to appear in firms with 500 or so employees. Five or six hundred workers are considered about the maximum size of work force that an owner-manager or a general manager can personally manage.

Three distinct features of employment practices in the internal labor-market sector are already well-known: lifetime employment, seniority wages, and enterprise-based and -confined labor unions. Quantitatively, firms in this sector show a higher degree of employment security and a more powerful role of the length of service as a wage determining factor than their U.S. counterparts. The prominence of the sector relative to the rest of the economy may be seen from more pronounced productivity and wage differentials by size of firm in Japan than in the United States (manufacturing census figures). These defining characteristics of labor market segmentation are not free of controversy, but a brief look at past events would leave far less doubt for Japan than for the United States about the plausibility of labor market segmentation as a real phenomenon.

Japan in 1920 was one of the five leading powers of the world. Its development was certainly that of a market economy, though with State guidance and participation. However, it was not yet a full-fledged "capitalist" development: the tardy growth of the labor market limited the growth of a proletariat much needed for exploitation by the capitalists. Japan's difficulty in generating a proletariat appropriate to a capitalist economy was attributed in large part to the nature of Japan's absolutist state under the imperial Constitution (1889–1947) as a family system, "meaning a [state] system of legal and political organization whereby the family is the major unit of social organization, is a legal personality in which property rights and duties are vested, and is represented externally by a family head who exercises wide powers of control over family members."

Before the Second World War, many large Japanese firms were family-owned or controlled. Their organizational form was *Zaibatsu*, a conglomerate of diversified enterprises held by interlocking directorates under a family-controlled holding company (or its equivalent). The four largest *Zaibatsu* were household names throughout the world: Mitsui, Mitsubishi, Sumitomo, and Yasuda. How families control giant firms even today can be seen from the examples of Matsushita and Toyota.

Company acculturation

During the postwar period into the 1970's, the transaction-cost minimizing advantages of "the family" metaphor weakened, and management could no longer depend upon worker incentives and discipline resulting from the shared image of the company as a family. Furthermore, the postwar family was no model for any organization that

---

Koji Taira is professor of economics and industrial relations at the University of Illinois, Champaign-Urbana. His full IRRA paper is entitled, "Labor Market Segmentation, Human Resource Utilization and Economic Development: The Case of Japan in Historical Perspective."

required authority and responsibility for getting work done.

The Japanese employment system that emerged from the consolidation of labor market may well be called "management by company culture." Culture now takes the place of erstwhile paternalism. It is well known that well-run Japanese companies are making constant efforts to shape and maintain a corporate identity that is distinct and unique enough to motivate employee identification with it. The culture-conscious Japanese companies devote enormous attention to the recruitment of compatible employees. The general practice is to recruit employees once a year in the spring, fresh out of schools or colleges, according to careful long-run manpower plans. These companies regularly hire from the nation's best universities and maintain a stable mix of employees by university origin. Blue-collar recruitment also runs by school or regional origin. Informal groups formed by college, school, or regional ties mesh with formal work groups. The "old boys" network is automatically stratified by year of graduation and can be used as an instrument for orderly acculturation and training of employees through senior-junior (*senpai-kohai*) relationships. Several "old boys" groups in a company also generate competition for performance among them. Each group probably desires to maximize its share in good positions and promotions. So long as personnel procedures and evaluations are objective and unbiased, competition among these groups may be channeled into higher aggregate performance (although it might also degenerate into dysfunctional office politics). The role of a company culture is to integrate competing groups and individuals into a harmonious whole to ensure the aggregate vitality of the firm.

The enterprise labor union also facilitates this cultural integration by taking up all nonmanagerial white-collar and blue-collar workers, regardless of their educational backgrounds. The union then can be viewed as a crucible of social democracy within the enterprise, although managers and organized employees of the internal labor-market sector as a whole constitute an elite of the labor force vis-a-vis the rest of the working population of the national economy.

Large versus small and medium

The modernization of "the family" and interpersonal relations within it since the postwar democratic revolution has proceeded unevenly in different socioeconomic strata. Studies of lower middle-class merchants and artisans indicate a strong survival of the prewar type of family and its application to employment relationships. Generally, small and medium-sized enterprises contitute a noninternal labor-market sector (the dual of the internal labor-market sector where the Japanese employment system obtains) and labor-market indicators like labor turnover, length of service, cyclical sensitivity of employment, and so forth which are those of relatively open, fluid labor markets. These enterprises obviously make up for the lower wages and less attractive working conditions than in the internal labor-market sector by offering a "psychic income" of a family atmosphere, familiar to their employees. Furthermore, employees in the noninternal labor-market sector are, in a sense, residuals, dropouts or failures vis-a-vis their peers picked by firms in the internal labor-market sector.

They are likely to be from the social strata which, because of their relative backwardness, have lagged in modernization and still retain relatively greater doses of traditional values and practices. The familiar syndrome of factors that generates "occupational inheritance" is also observed in Japan.

From a different point of view, the employers and employees in small and medium-sized enterprises are the average Japanese, and those in the internal labor-market sector, an exception. On the basis of employment statistics by establishment size, regular employees in private establishments (employing 500 or more regular employees), public enterprises, and civil service amounted to 16 percent of the Japanese labor force in 1981. This is roughly the size of the internal labor-market sector in Japan by sheer head count (9 million). The smallness of this sector enables it to choose the cream of the crop. The employees of this internal labor-market sector themselves are also conscious of their elitist position. The labor market segmentation of this kind does not generate the classic classes of capitalists (or corporations) and workers with distrust, misgivings, or even animosity between them. The major divide is between large bureaucratized firms in this sector and the small and middling enterprises, mostly family-run or -controlled, in the noninternal labor-market sector. Tensions exist and occasionally flare up between large firms and small firms as in the case of an organized protest by local store owners against the plan of a large national distributor to open a branch in their midst. Large firms have long since realized the limits to direct expansion at the expense of smaller firms and, instead, actively organized the smaller ones into networks of close business relationships known as *Keiretsu* (lining them up). However, the transaction costs in getting things done through a *Keiretsu*, involving hundreds of smaller, but independent firms, are apparently lower than the large firm itself expanding in the equivalent scale to internalize the network. Thus, some workable peace obtains between large and small firms. It is noteworthy that resilience and political sophistication of small firms limit the physical growth of large firms and direct the attention of the latter to "social" leadership over a multiplicity of lesser firms.

The employees of the internal labor-market sector are organized into enterprise employee unions and largely coopted into a sharing system of the elite sector through collective bargaining and joint consultation. Enterprise unions see no community of interest with the unorganized employees of smaller enterprises as exemplified by an almost total absence of effort on the part of the established unions to organize the unorganized. The basic behavioral determinant is the union's "enterprise consciousness" meaning that for their well-being, employees depend on their employer's prosperity and that the union's role is to ensure a "fair share" in the employer's prosperity.

With no horizontal (class) solidarity among workers, employees in the noninternal labor-market sector perceive themselves as being in the employee status only as long as they learn the skills and accumulate the resources to strike out on their own. This "Japanese dream" does not become a reality for a majority of wage-earners in this sector, but it does for a substantial number of them, who set and maintain the entrepreneurial propensity. For a major capitalist-market economy, Japan still has an unusual proportion of the labor force in self-employment (together with family workers, 27 percent of the labor force in 1981) and an unusual proportion of the nonagricultural private regular employment in the smallest establishments with fewer than 30 employees (48 percent in 1981).

For more than half of Japan's economically active population, "employer" and "employee" do not imply sharp status differences, let alone "class consciousness." Where class consciousness should have arisen, and did for a while after the war, namely the internal labor-market sector, *employees* are the secure members of the nation's elite. Labor market segmentation has thus created in Japan a social stratification that the known formulae of differentiation have difficulty in explaining. However, the upshot of certain developments in Japan: inflation; employment cutbacks, despite lifetime employment; more extensive use of part-time, temporary, or seasonal workers; equal employment opportunity legislation for women; the raising of the mandatory retirement age from 55 to 60; and weakened union activity at the enterprise level (causing them to turn to national consolidation and economic policy) is the prospect of less segmentation. The internal labor markets of major firms cease to be the monopoly of standard male regular workers, recruited fresh out of schools and colleges with expectations to serve out their term until mandatory retirement. ☐

How do Australian unions maintain standing during adverse periods?

JOHN NILAND

Australian unions are organized on a craft or occupational basis, much more than along industry or enterprise lines as in the United States. Because unions typically enroll members from more than one industry, workers in a medium-sized factory of 500 or so typically will be covered by 5 to 10 unions: the production or process workers gravitate to 1 or 2 unions, white-collar and clerical people go to another, and maintenance personnel join a further group of unions. Also, supervisors and front-line managers increasingly have been joining trade unions, primarily from fears generated by increased redundancy and corporate rationalization, but also as a defense mechanism against the growth in industrial democracy practices which supervisors often perceive as a challenge to their own job territory. Overall, 320 unions are registered within the tribunal system.

Australian trade unionism has continued to be a numerical force in the past decade, although the two main sets of official statistics indicate marginally contradictory trends. One set of data is based on a labor market survey of employees in 1976 and again in 1982. Unionization declined slightly from 51 percent to 49 percent, with women maintaining a rate at 43 percent and that for men decreasing from 56 percent to 53 percent. The alternate official series, with statistics collected annually from the trade unions themselves, shows that the overall union participation rate increased slightly from 56 percent in 1975 to 57 percent in 1982.

Unionization by industry

An analysis of industry shift in unionization between 1976 and 1982 reveals that, as in some other industrialized market economies, the manufacturing sector is in some difficulty with a drop of 3 percentage points, entailing a loss of some 45,000 unionists. Debate over the causes covers many possibilities, including deindustrialization through crowding out by the nonmarket sector or through the influence of multinational companies; the Gregory Thesis of booming minerals sector deindustrialization; and the Cambridge Effect, involving exports and balance of payments problems. These lines of argument have little to do with unions directly, although two other schools of thinking do: the rise of inefficient protection policy which itself is linked to wages policy that emphasizes standardization and uniformity; and the real wage overhang effect through which many wage rises in the past decade have outstripped appropriate productivity movements. Whatever the primary cause, unionism in its most important sector has lost ground. However, this is almost offset by a 3-percentage-point rise in the incidence of community services employment. Unionism has made distinct gains in the wholesale/retail area, and has held its own in the finance/insurance business services sector. In both cases, negotiation of compulsory unionism agreements has been important. For example, the union participation rate in the private banking industry had been 57 percent in 1973, but toward the end of that decade it had risen to 84 percent with the introduction of a closed shop arrangement.

The labor market

The unionization picture is particularly noteworthy in the light of movements in Australian unemployment figures. From a rate of 2.4 percent in 1974, unemployment peaked in 1983 at 9.9 percent, thereafter dropping to 7.9 percent in

---

John Niland is a professor and head of the Department of Industrial Relations, University of New South Wales, Australia. His full IRRA paper is entitled, "Gaining Against the Tide: Australian Unionism in the 1980's."

1985. As one researcher points out, few Australian unions provide advantages that would encourage displaced workers to maintain membership:

> . . . unlike some United States unions . . . few Australian unions act as employment centers; nor do they provide unemployment or other benefits. This, together with the fact that most forms of . . . union shops are confined to a small number of industries, means that unemployed workers usually see little point retaining union membership.

However, Australian unions have held their membership coverage despite considerable erosion of their recruitment base by unemployment. Indeed, a leading school of thought contends that unions have preserved their position at the expense of the unemployed, particularly the hardest hit category of youth, whose rate of unemployment rose from 5.8 percent in 1974 to 22.6 percent in 1983.

The age profile on unionization trends is important in the sense that disenchantment among the young could herald future difficulties. At first sight, Australian unions might well be concerned on this score, as the membership incidence varies sharply with age cohort: the figure in 1982 for youth (15 to 19 years) was 31 percent, compared with 44 percent for young adults (20 to 24 years) and 53 percent for adults (25 and over). However, up to 5 percentage points of the gap between youth and adult unionization may be accounted for by the fact that apprentices (an avenue through which 25 percent of all boys enter the labor market) traditionally are nonunionized. Another factor is the tendency for youth to concentrate in low unionized sectors, such as wholesale/retail trade and entertainment: "If manufacturing is excluded, differences in the employment composition between teenagers and adults account for half the difference in their unionization." Finally, high turnover rates among young employees, who in adulthood presumably will settle down, is also a significant factor for lower youth unionization rates.

Wages and conditions

The Australian system of industrial regulation is based on the process of conciliation and arbitration which entails government-appointed tribunals determining wages and other conditions of employment. Because the industrial tribunals have official standing and operate in a semijudicial environment, the propensity for standardization and centralization is strong. These pressures have been particularly pronounced in the past decade.

Commencing in March 1975, the Australian Conciliation and Arbitration Commission (hereafter Arbitration Commission) has awarded wage increases to closely reflect movements in the Consumer Price Index, the main indicator of inflation. Of the 19 National Wage Case decisions in the Indexation Era, the Arbitration Commission awarded full CPI adjustments on 7 occasions, with the remainder producing either partial percentage adjustment or some plateauing arrangement in which only those from lower paid classifications received real wage maintenance. Inevitably, this led to compression of skill margins, particularly as it was the stronger unions covering such groups as transport workers and open cut coal miners rather than those covering trade classifications which managed to breach the Arbitration Commission's "substantial compliance" guideline, and negotiated privately to achieve wage increases beyond the national minima. In the end, too many groups were running outside the national guidelines, and in July 1981, the Arbitration Commission abandoned the Indexation Era, leaving the parties to a form of disheveled bargaining.

Indexation had been introduced in 1975 to help spike wage expectations which at that time were beginning to run rampant. Fears were held of a repetition in 1982, and with all parties increasingly cautious in light of a forthcoming election, the Federal Government managed to sell the idea of a wage pause. So crucial are industrial relations issues to political fortunes in Australia that the subsequent success of the Australian Labor Party in the March 1983 election owes much to its deal with the Australian Council of Trades Unions to re-introduce an orderly wage fixing arrangement. The Prices and Incomes Accord provided the way for a return to centralized wage fixing, and by September 1983, the Arbitration Commission had worked out a set of guidelines to put the arrangement into operation. This virtually guaranteed full CPI wage adjustment, although now the interdiction on groups negotiating private deals beyond the national standard became much more effective. Even so, classification creep and some increase in overtime enabled average weekly earnings to keep ahead of inflation. The period between 1971–72 and 1982–83 saw substantial wage increases, with money wage aggregate growth of 129.9 percent well outstripping the aggregate CPI growth of 111.1 percent.

A significant development in the decade to 1985 has been the growing authority of the Australian Council of Trade Unions in national wage policy. In the mid-1970's, this peak union body resisted, unsuccessfully, maneuvers of the Whitlam Labor Government and the Arbitration Commission to locate wage fixing back within the Arbitration Commission. Initially, wage indexation meant holding wage increases below their recent trend line; 10 years later, with rising unemployment and the salutory effect of the economically awkward Whitlam years (1972–75), the council came to see considerable merit in CPI-linked wage adjustment, particularly as it became the joint-administrator in the transformed central system.

These developments hardly suggest a labor movement losing ground in the face of economic adversity, as much as theory might suggest such would be the outcome. What is perhaps more important, the growth of real wages in such difficult times was not achieved through trading off other conditions: not since the early 1930's have the industrial tribunals attempted to meet unemployment concerns with across-the-board reductions in industrial conditions, and only in isolated instances do they now roll back provisions for particular firms in trouble. Indeed, over the past decade, unions have made gains in various nonwage conditions, which further reflect unionism's enhanced standing. Perhaps most important has been the 35-hour week campaign. Begun in the mid-1970's, shorter hour gains were widespread by the early 1980's, although many groups eventually had to settle for 38 hours as their new regular working week. This is now the standard accepted by the Arbitration Commission, although cost savings through revised work practices are a mandatory quid pro quo. This arrangement—the linking of work efficiency to further reduced hours—is perhaps one of only two developments in the formal industrial relations system over the past decade with appeal to employers. The other is the emergence of the no-further-claims clause by which unions agree to hold the line on wage claims for a designated period, and in other ways, to abide the agreements.

Several other sets of improved conditions should also be mentioned. While Australia lagged much of Europe in the provision of job protection, advance notice of redundancy, and compensating termination packages, a 1984 decision of the Arbitration Commission in the Termination Change and Redundancy Case, changed the picture somewhat. Also, as part of its accord commitments, the Australian Government in 1984 established the National Occupational Health and Safety Commission to "develop national standards and priorities, upgrade research and training efforts, and provide a basis for unions and employers to work together to make workplaces safer." Another development linked to the accord is the program to more widely infuse industry with the precepts and practices of industrial democracy, although here the main initiatives will be in the Accord Mark II (1985–87) more than in the Accord Mark I (1983–85). The same can be said for the introduction of nationwide superannuation schemes, due to start in July 1986, where all unionists will have 3 percent of their wages paid by their employer into the pension fund of the worker's choice. The arrangements for pension trust management, yet to be finalized, could give unions the basis for further enhanced standing. □

Research Summaries

Aggregate export price comparisons developed for U.S., Germany, Japan

DAVID S. JOHNSON

In February 1986, the Bureau of Labor Statistics began producing aggregate export price index comparisons between the United States and Japan and the United States and Germany on a quarterly basis. Previously, BLS had been producing export price index comparisons only for detailed commodity categories.

Export price comparison measures are ratios of the foreign export price indexes in dollar terms to specially calculated U.S. export price indexes. The measures, in index form, are designed to show relative price movements between the United States and Germany and the United States and Japan for designated market baskets of products.

An increase in a comparison index represents an increase in the price of the foreign export basket of goods compared to the U.S. price of an export basket consisting of the same volume and similar types of commodities. The opposite is true in the case of a decrease in an index. Changes in relative price movements are of interest because of their influence on changes in relative export quantities.

Comparison measures are calculated by first translating the foreign export price indexes into dollar terms and then dividing these indexes by the special U.S. export price indexes matching the foreign export categories.[1] The exchange rates used in converting the foreign price indexes to dollar terms are monthly averages of certified noon buying rates in New York as published by the Federal Reserve Board.[2]

The indexes for periods in which different export value weights were used have been linked together. The German-U.S. export price index comparisons use 1970 German export value weights from June 1970 through March 1976; 1976 weights from June 1976 through December 1979; and 1980 weights from March 1980 to the present. The Japan-U.S. export price index comparisons have been calculated using 1975 Japanese export value weights from June 1970 through December 1979, and 1980 weights from March 1980 to the present.

The comparison measures have been aggregated according to foreign country export trade weights in order to match the classification systems of the published foreign export price indexes.[3] Other weighting schemes, such as the use of U.S. export trade weights or world trade weights, would produce different results. Aggregating according to other weighting schemes would require access to price data for individual export commodities from Germany and Japan which are not available at the present time.

German export price indexes are published by the Statistisches Bundesamt [Federal Statistical Office] of the Federal Republic of Germany in the monthly publication, *Preise und Preisindizes fuer die Ein- und Ausfuhr* [*Prices and Price Indexes for Imports and Exports*]. The German export price indexes used in the comparison measures are taken from table 2.6 for the detailed product categories and from table 2.5 (SITC, Rev. II) for the aggregate categories. Currently, Germany calculates its export price indexes from approximately 6,100 individual export price series. These prices refer to export transactions concluded during the reporting month for specified commodities on an F.O.B. (free on board) German border basis, and are adjusted for quality changes. Individual price relatives are aggregated by means of the Laspeyres formula using export value weights.

The Japanese export price indexes used in the comparison measures are taken from Section II, table 3 of *Price Indexes Monthly*, published by the Bank of Japan. This table contains 319 export categories at different levels of aggregation. Approximately 530 export prices are surveyed by the Bank of Japan on a monthly basis. These prices are contract prices on an F.O.B. port basis and are adjusted for quality changes. The individual price relatives are aggregated as above using Japanese export value weights.

The specially constructed U.S. export price indexes used in the comparison measures have been designed to match the commodity coverage of the German and Japanese published export price indexes. The price series used in these indexes have been selected from approximately 7,700 export prices collected from U.S. exporters by the Bureau of Labor Statistics' International Price Program. The prices collected are either F.O.B. or F.A.S. (free alongside ship) transaction prices which are adjusted for quality changes. The individual price relatives are aggregated by means of the Laspeyres formula using the respective foreign export trade weights.

The Statistisches Bundesamt, producer of Germany's export and import price indexes, has furnished BLS with a table

---

David S. Johnson is an economist in the Division of International Prices, Bureau of Labor Statistics.

of weights and subclassifications within its published export price index categories. By using this information along with the description of Germany's Commodity Classification for Industrial Statistics (WI),[4] it was possible to select export products collected by the BLS International Price Program which were judged to be similar to the products represented in the German published series. A similar procedure was used for the correct classification of U.S. products within the Japanese classification scheme. The Bank of Japan supplied BLS with a complete listing of product specifications used in the production of Japanese export price indexes. From this listing it was possible to construct special U.S. export price indexes with comparable commodity coverage.[5]

In regard to product coverage, it should be noted that the BLS export price data base is a sample designed to represent U.S. export price trends at the level of 4- or 5-digit SITC (Rev. II) product categories. Although a selection of export prices from this data base has been used to produce the special U.S. export price indexes for the comparison measures, the product samples were not originally drawn for this purpose. However, the mappings of products to foreign export categories have been thoroughly examined to ensure the fullest product coverage possible.[6] □

Research Notes

Measuring wage premiums for job risks

During the past 10 years, a large amount of research has been devoted to measuring the wage premiums which workers receive as a result of bearing additional occupational injury and illness risks. Improved estimates of the premiums are of value for policy evaluation because they are used to assess the benefits of proposed occupational safety and health regulations.

The motivation for this research is the idea that, in general, if a worker has a choice between two jobs of different riskiness, he will choose the riskier one only if it pays a sufficiently higher wage. The wage premium for bearing extra risk is known as a compensating wage differential, because the premium is viewed as being paid to compensate for the additional riskiness. A compensating differential should not be confused with workers' compensation benefits. The former is paid as a component of wages, while the latter is an indemnity benefit paid only if a worker is injured. They are related, however, in that both are paid to compensate a worker for the costs he bears in the event of an injury or illness.

Research on measuring compensating differentials endeavors to explain observed variations in wages by means of an equation which relates worker and job characteristics to wage levels. Let W represent the wage level, X represent worker and job characteristics known to affect wages, such as education or experience, and let R represent the riskiness of a job. It is hypothesized that wages are related to X and R through the equation

$$W = a + bX + cR$$

where b and c are coefficients which indicate by how much wages change with unit increases in X and R. For example, suppose that R measures the number of injuries and illnesses incurred by 100 workers in 1 year, that W measures weekly wages, and that c has a value of 5. Then the equation indicates that an increase in the riskiness of a job of 1 case per 100 workers per year is associated with an increase in weekly wages of $5. The object of empirical work on compensating differentials is to obtain better estimates of c from data sets containing information on wages and worker and job characteristics.

In a recent paper, we examine two issues in the measurement of compensating differentials. First, we study to what extent the differentials differ for men and women and for union and nonunion workers. Second, we analyze the impact of including a measure of workers' compensation benefits in the wage equations used to estimate the differentials.

The primary source of the data was a sample of private nonagricultural blue-collar and service workers drawn from the May 1980 Current Population Survey. Separate wage equations were estimated for union men, nonunion men, union women, and nonunion women. Standard education, experience, and demographic characteristics were included as X variables in the wage equations. In addition, two measures of job risk and a measure of workers' compensation benefits were included as variables explaining wage variations. The job risk variables, obtained from the Bureau of Labor Statistics' 1980 Annual Survey of Occupational Injuries and Illnesses, measure the number of lost workday injury and illness cases per 100 full-time workers and the number of lost workdays per lost workday case. These measure the frequency and severity of injury and illness cases by industry, respectively. The workers' compensation variable measures the proportion of weekly wages replaced by total temporary disability benefits. It was imputed from information on the workers' weekly wages and characteristics and the State laws regarding benefit payments.

Three principal conclusions emerge. First, there is strong evidence of compensating wage differentials for both union and nonunion men. Men receive higher pay to work at riskier jobs; for women, however, the evidence is not as conclusive. Only female union members appear to receive higher wages for riskier jobs, and even here the evidence is not as strong as for men. It is conceivable that the lack of evidence for women suggests that they indeed do not receive wage premiums for job risk. It is equally possible, however, that the poor results for women suggest that the industry job risk variables, which are not available by sex, do not adequately represent the job risks faced by female employees of high-risk industries. Women tend to be underrepresented in these industries and, within them, they tend to work in the low-risk occupations.

A second finding of the research is that, everything else being the same, an increase in the proportion of wages replaced by workers' compensation income benefits leads to a drop in the wage level. This result is stronger for women than for men. A final surprising result is that the inclusion of the workers' compensation benefit variable in the wage equations has no effect on estimated compensating wage differentials. Also, coefficients on the interaction of workers' compensation benefits with the risk variables are generally statistically insignificant.

The study and its results are described in full in the paper "Workers' Compensation Benefits and Compensating Wage Differentials," by John W. Ruser, BLS Working Paper No. 153.—*John W. Ruser, Office of Research and Evaluation, Bureau of Labor Statistics.* □

Interview group bias

In the Current Population Survey, like many data sets used in studies of labor force behavior, respondents are interviewed repeatedly. Previous research has shown that responses systematically differ with the number of times that individuals are interviewed. With the current and growing emphasis on dynamic models of labor force behavior and the increasing use of panel data, it is important to examine the quality of the data and potential survey response error that can be confounded with the measurement of systematic changes in behavior over time.

Empirical estimates of time-related bias in the Current Population Survey (CPS) have grouped together all respondents who enter the sample at the same time. In the CPS, these groups are referred to as rotation groups. This procedure requires the implicit assumptions that respondents never miss interviews and that there is no mobility in and out of the sample. If these assumptions are not supported by the data, they can lead to significant underestimates of time-related effects on reported labor force status.

Microdata from the CPS are used to provide empirical evidence of the effects of repeated interviewing on survey responses. Using 3- and 4-month matches of three different rotation groups from the CPS, we found that a substantial number of respondents have not been surveyed in every month. Respondents who have been interviewed the same number of times are classified as members of the same interview group. Estimates of the magnitude of bias within these rotation groups of the CPS show that the unemployment rate for respondents interviewed for the first time can be more than 50 percent higher than for respondents interviewed for the fourth time. The paper includes a discussion of the relative importance of rotation group bias and interview group bias in the CPS and concludes that interview group bias can explain the patterns of rotation group bias commonly observed. While this research focuses only on the CPS, the same types of problems may arise in any panel data set.

The study and its results are described in full in the paper "Interview Group Bias: Effects of Repeated Interviewing on Estimation of Labor Force Status," by Janice Shack-Marquez, BLS Working Paper No. 154.—*Janice Shack-Marquez, Office of Research and Evaluation, Bureau of Labor Statistics.* □

Major Agreements Expiring Next Month

This list of selected collective bargaining agreements expiring in July is based on information collected by the Bureau's Office of Wages and Industrial Relations. The list includes agreements covering 1,000 workers or more. Private industry is arranged in order of Standard Industrial Classification.

Employer and location	Industry or activity	Labor organization[1]	Number of workers
Private			
Iron Ore Mining Companies (Interstate)	Mining	Steelworkers	3,000
Climax Molybdenum Co. (Climax, CO)	Mining	Oil, Chemical and Atomic Workers	2,000
Nassau and Suffolk Contractors Association (New York)	Construction	Laborers	2,000
Association of Mechanical Contractors (Georgia)	Construction	Plumbers	1,150
Construction Industry Combined Committee and 2 others (St. Louis, MO)	Construction	Iron Workers	1,200
Mechanical Contractors Association (Utah)	Construction	Plumbers	1,000
Miller Brewing Co. (Milwaukee, WI)	Food products	Brewery Workers	1,000
Michigan Sugar Co. (Michigan)	Food products	Grain Millers	1,200
E.J. Brach & Sons, Inc. (Chicago, IL)	Food products	Teamsters (Ind.)	3,000
Winery Employers Association (California)	Food products	Distillery Workers	3,500
Southern California Cabinet Manufacturers (California)	Furniture	Carpenters	1,500
Kimberly-Clark Corp. (Tennessee)	Paper	Paperworkers	1,000
Weyerhaeuser Co. (Plymouth, NC)	Paper	Paperworkers	1,600
James River Co., KVP Division (Michigan)	Paper	Paperworkers	1,000
James River Co., Board and Carton Division (Michigan)	Paper	Paperworkers	1,200
Hammermill Paper Co., Thilmany Pulp & Paper (Wisconsin)	Paper	Paperworkers	1,250
Phoenix Steel Corp. (Interstate)	Primary metals	Steelworkers	1,000
Armco Steel Corp. (Butler, PA)	Primary metals	Butler Armco Independent Union (Ind.)	2,000
Armco Steel Corp. (Ohio)	Primary metals	Armco Employees Independent Federation (Ind.)	4,800
Martin Marietta Aluminum Inc. (Interstate)	Primary metals	Steelworkers	1,900
FMC Corp., Northern Ordnance Division (Fridley, MN)	Fabricated metals	Auto Workers	2,200
Briggs and Stratton Corp. (Milwaukee, WI)	Machinery	Industrial Workers	8,200
Caterpillar Tractor Co. (Joliet, IL)	Machinery	Machinists	1,300
Sealed Power Corp. (Muskegon, MI)	Machinery	Auto Workers	1,000
Eltra Corp., Prestolite Division (Interstate)	Electrical products	Auto Workers	1,200
Hayes International Corp. (Birmingham, AL)	Transportation equipment	Auto Workers	2,200
Pacific Coast Shipbuilding and Ship Repair Firms (Interstate)	Transportation equipment	Various	10,000
Rouge Steel Co. (Michigan)	Transportation equipment	Auto Workers	15,000
Frontier Airlines, agents (Interstate)[2]	Air transportation	Air Line Pilots	2,400
Brooklyn Union Gas Co. (New York)	Utilities	Transport Workers	2,200
Ohio Edison Co. (Ohio)	Utilities	Various	2,100
Food Employers Association, Inc., warehouse (Oregon)	Wholesale trade	Teamsters (Ind.)	1,700
Montgomery Ward Co. (Interstate)	Retail trade	Teamsters (Ind.)	9,600
Fred Meyer Inc. (Portland, OR)	Retail trade	Food and Commercial Workers	1,700
Association of Private Hospitals (New York, NY)	Hospitals	Service Employees	7,000
Public			
Illinois: Cook County Community College, faculty	Education	Teachers	1,400
Maryland: Baltimore police	Law enforcement	Police	2,500
Iowa: Des Moines Independent Community School District, professionals	Education	Education Association (Ind.)	2,000
Michigan: Wayne State University, faculty	Education	University Professors (Ind.)	1,400
Tennessee: Chattanooga Board of Education, teachers	Education	Education Association (Ind.)	1,500
Texas: Houston Metropolitan Transit Authority	Transit	Transport Workers	1,450

[1] Affiliated with AFL-CIO except where noted as independent (Ind.).

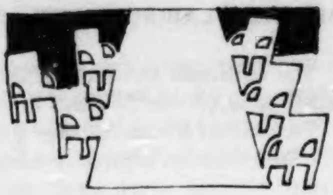
Developments in Industrial Relations



First of the steel contracts

The first round of negotiations in the steel industry since the 1985 breakup of the Coordinating Committee Steel Companies, the industry's pattern-setting bargaining association, led off with settlements at LTV Steel Co. and National Steel Corp. In keeping with the Steelworkers acknowledgment that the severity of problems afflicting the industry varies among the companies, the union agreed to different terms at LTV Steel and National Steel.

In the past, the Coordinating Committee Steel Companies, comprising U.S. Steel Corp. and other large companies, had negotiated uniform terms that were followed by nonmember companies. Deviation from the pattern terms occurred in 1985 when Wheeling–Pittsburgh Steel Corp. negotiated a substantial permanent cut in wages and benefits. Afterwards, U.S. Steel and other producers said that in their 1986 negotiations, they would seek similar compensation cuts in order to maintain production cost parity with Wheeling–Pittsburgh. Steelworkers' President Lynn Williams said the union would tailor each settlement to the condition of the particular company.

At LTV Steel, which has suffered $1.7 billion in operating losses since 1982, including $227 million in 1985, the union agreed to a $3.15 cut in hourly compensation—a $1.14 cut in pay and a $2.01 cut in benefits. The company estimated that an additional 45 cents an hour would be saved in indirect costs because it will pay less social security and other taxes and benefits from lower administrative costs, bringing its total savings to $3.60. In addition to the pay cut, the employees will forgo the final increment of the pay restoration required to bring wages back to the level that prevailed prior to the 1983 settlements, which called for a temporary pay cut of $1.25 an hour. The final increment (45 cents an hour) was restored to employees of the other companies on February 1, 1986, as scheduled, but the payment date had been postponed to April 1, 1986, at LTV Steel as a result of a 1986 contract modification. (See *Monthly Labor Review*, April 1986, p. 57.)

In return for the $3.15 in direct savings, LTV agreed to a Profit-Sharing and Stock Ownership Plan that will give the employees a "dollar-for-dollar payback in equity" for their sacrifice. A union official noted that the accord provides for "guaranteed job security opportunities and more worker involvement in decisionmaking at all levels of company policy."

Other cost cuts accepted by the union include:

- A reduction in shift premiums to 20 cents an hour, from 30 cents, for the second shift and to 30 cents, from 40 cents, for the third shift.
- Suspension of the cost-of-living pay adjustment provision.
- Elimination of 3 of the 10 paid holidays.
- Elimination of 1 week of paid vacation for all employees currently eligible for at least 2 weeks.
- Elimination of vision care benefits.
- A reduction in sickness and accident benefits, to a range of $175–$229 a week.

Employees weekly pay statements will now indicate their accumulating wage and benefit sacrifices. In April of each year, they will receive the accrued value from company profits, if any. The cash available for distribution will equal 10 percent of the first $100 million of LTV Steel profits plus 20 percent of all profits in excess of $100 million. If profits are insufficient, workers will receive the balance in dividend-bearing shares of the LTV Steel preferred stock. After 2 years, the shares can be sold or exchanged (at $16 a share) for common shares of the parent LTV Corp.

One of the major issues in the negotiations was resolved by adoption of a restriction on subcontracting of work (except construction) if it can be performed by members of the bargaining unit. To bypass this restriction, the company must prove that proposed subcontracting is consistent with past practice and the work must pass a "reasonableness test," excluding comparisons of costs.

Also in return for the wage and benefit cuts, LTV Steel agreed to a program of monitoring overtime levels and to give the local union a monthly accounting of the amount and reasons for overtime work.

In a related job security provision, the company agreed not to sell or transfer a plant covered by the agreement unless the new owner recognizes the unit as bargaining agent. Also, the new owner must negotiate an agreement acceptable to the union before the sale can be completed.

"Developments in Industrial Relations" is prepared by George Ruben of the Division of Developments in Labor-Management Relations, Bureau of Labor Statistics, and is largely based on information from secondary sources.

The settlement covered 30,500 employees—including 8,500 on layoff—in 24 plants in seven States.

The contract at National Steel differed markedly from the LTV Steel contract, apparently reflecting National's smaller losses. National, which is half owned by the Nippon Kokan KK steel company of Japan, lost $88 million in 1985, including $27.2 million in the fourth quarter. Reportedly, National Steel did not require compensation cuts as large as LTV Steel because National has already closed a higher proportion of its inefficient facilities.

The 39-month accord provides for a 42-cent-an-hour pay reduction, including suspension of the 11 cents cost-of-living adjustment that was effective February 1, 1986. The employees will receive no further cost-of-living-adjustments during the agreement, but will receive annual bonuses under a new profit-sharing plan. The distributions will range from 50 cents per hour worked during the year if the company loses money to a maximum of $1.75 per hour if its net income is $300 million or more.

The workers also will be eligible for quarterly bonuses based on future increases in productivity. The separate plans at each of the three locations are based on any local increase in tons shipped per worker, local cuts in the work force, and corporate-wide cuts in the work force. These three factors, weighted 30, 20, and 50 percent, will be compared with a base level to determine possible improvements in productivity. The quarterly payouts will range from 1 percent of each employee's pay if productivity rises 1 to 5 percent to 17 percent if the rise is 60 percent.

From the union's viewpoint, probably the most important contract provision is a new employment security plan which prohibits layoffs during the contract term. Workers who would otherwise have been laid off will be placed in an employment security pool for retraining or for a new assignment.

In another change important to the employees, the contract provides that "work capable of being performed by bargaining unit members shall be performed by [them]." Further, the company cannot contract out work "unless it demonstrates that such work meets one of the [limited] exceptions." Similarly, contractors can not perform work in the National Steel plants unless the work has consistently been performed by contractors in the past and the company can prove that it is more reasonable for the contractor than plant employees to perform the work.

Other contract terms include—

- Tighter restrictions on use of overtime.
- Assurances that sacrifices of employees not in the bargaining unit will equal those made by employees in the unit.
- Personnel reductions only by mutual agreement and then only by attrition.
- A Cooperative Partnership Agreement calling for the creation of joint committees to solve problems quickly and in a cooperative manner.
- Adoption of a cost containment program for health care benefits.
- Elimination of the company's 25-cent-an-hour payment into the Supplemental Unemployment Benefits fund until it is drawn down to its required level. At the time of settlement, the fund was at 200 percent of the required level.

Although not a part of the basic agreement, another important development during the negotiations was National Steel's confirmation that it planned to continue a 5-year, $1.2 billion capital investment plan started in 1985.

The 7,200 workers covered by the accord are employed by three National Steel subsidiaries located in Illinois, Indiana, and Michigan. They are Midwest Steel, Great Lakes Steel, and Granite City Steel.

General Telephone contract 'concession-free'

The first settlement in the 1986 round of bargaining in the telecommunications industry occurred when General Telephone Co. of California and the Communications Workers of America (CWA) agreed on a 3-year contract for 20,000 workers. Based on past practice, the settlement was expected to set a pattern for 30,000 employees of other General Telephone companies. It also could influence the CWA's current bargaining with American Telephone and Telegraph Co. and the various operating and manufacturing companies resulting from the court-ordered 1984 breakup of the Bell Telephone System. CWA President Morton Bahr said the most important aspect of the accord was its "concession-free" nature, which would also be the guiding principle in the union's talks with the former Bell System companies.

Bahr said the key to the settlement was General Telephone's withdrawal of its demands for adoption of a two-tier pay system and a provision automatically raising employee deductibles under the health care plan as premiums rise. Instead, deductibles were raised by a fixed amount and a joint health care cost containment committee was established.

The contract, running to March 5, 1989, provides for wage increases of 3 percent retroactive to March 5, 1986, and 2 percent in September of 1987 and 1988. Some employees will receive additional increases as a result of job reclassifying.

More railroad accords

The prolonged round of bargaining in the railroad industry inched closer to a conclusion when the Brotherhood of Railway and Airline Clerks (BRAC) settled with the 25 major carriers represented by the National Railway Labor Conference. The 4-year accord provided for smaller general wage increases but larger lump-sum payments than those negotiated in October 1985 by the United Transportation Union. (See *Monthly Labor Review*, January 1986, pp. 7–8.)

Announcing that 85 percent of BRAC members had voted in favor of the 4-year contract, union president Richard I. Kilroy called the negotiations "the toughest. . . I've ever had in my years in rail labor. I believe this contract is the absolute best we could obtain in today's tough economic and political climate."

The contract is retroactive to the June 30, 1984, date when wage and benefit terms were subject to change. It provides for lump-sum payments of $565 within 60 days of ratification, $335 on December 15, 1986, and $217 on June 15, 1988. The specified pay increases are 2 percent retroactive to December 1, 1985, and 2.25 percent on December 1 of 1986 and 1987. The increases will raise the average hourly clerical pay rate to $13.94, from $13.08. The 85,000 workers covered by the accord also will continue to be eligible for possible semiannual cost-of-living pay increases of up to 8 percent a year, offset by the value of the specified pay increases and lump-sum payments during the year.

New employees will start at 75 percent of the standard rate for their job and progress to the standard rate in annual 5-percentage-point steps. Previously, workers started at 80 percent and attained the standard rate after 2 years of service. In a related action, a commission was established to determine if current clerical pay rates are too high or too low.

Other provisions included the formation of a joint committee to study health care cost containment.

It was not clear when the other 11 unions would settle with the carriers. The Brotherhood of Locomotive Engineers, which had rejected an earlier tentative accord, was in arbitration under provisions of the Railway Labor Act, and the other unions were negotiating.

Growers, pickers end 8-year dispute

A dispute noted for its duration and the number of parties involved ended when Campbell Soup Co., tomato and cucumber growers in Ohio and Michigan, and the Farm Labor Organizing Committee agreed on new labor contracts for 550 workers. The dispute began in 1978, when the Committee began pressing Campbell Soup to support its efforts to organize employees of the growers, who sell their crops to Campbell. Campbell disagreed, contending that any collective bargaining relationship should be strictly between the farmers and the Committee.

As a result, the Committee instituted a boycott of Campbell products that was joined by the AFL-CIO and other organizations. The boycott was ineffective, according to a company public relations director, but in 1985, the company and the Committee agreed on elections in which the workers voted to be represented by the Committee. Contract negotiations then began, assisted by a five-member mediation panel headed by former Secretary of Labor John T. Dunlop. The panel was selected by the National Council of Churches, which will continue to assist the bargainers during the course of the new contracts by conducting representation elections at growers not now covered by the agreements. Expenses of the panel were covered by the Carnegie Corp. and further expenses will be covered by a grant from the William Penn Foundation.

The nearly 3-year agreement signed by Campbell, the Farm Labor Organizing Committee, and the Campbell Tomato Growers Association provides for wage rates for hand pickers to be set through further negotiations, and referred to the Dunlop panel if not settled by June 15, 1986. Machine harvesters receive $4.50 an hour for the 1986 season, increasing to $4.60 for the 1987 season. Other terms for the 150 employees in Ohio cover grievance procedures, dues checkoff, union recognition, housing conditions, day care, health and safety programs, and a joint study of the effect of pesticides.

A nearly 4-year cucumber contract between Vlasic Foods, Inc. (a Campbell subsidiary) and the Committee covers 400 workers in Michigan. It includes grievance procedures, dues checkoff, and other terms similar to the tomato contract.

The cucumber pickers will continue to receive basic pay equal to 50 percent of the gross value of the crop. In addition, they will now receive bonus compensation, contingent on a rise in cucumber prices. The size of the bonus will increase over the term. For the 1989 season, the possible bonus will range from 6 to 9 percent of basic pay.

Transportation Union leaves AFL–CIO

The United Transportation Union has disaffiliated from the AFL–CIO. In the letter of withdrawal to AFL–CIO President Lane Kirkland, Transportation Union President Fred A. Hardin attributed the action to a recent decision against the union under the Federation's procedures for resolving interunion disputes over organizing workers; the election of a Federation official to head a group supporting coal-slurry pipelines, which the union opposes; alleged Federation support of a plan for purchasing Conrail that the Transportation Union did not favor; the Federation's adoption of new regulatory procedures viewed as inimical to the union's organizing efforts; and opposition to some of the Federation's political endorsements.

In response, Kirkland contended that the Transportation Union had misconstrued the Federation's position on some of the points, or that the position was not a major threat to the union. He maintained that their differences are reconcilable and that he was hopeful that the Transportation Union might someday rejoin the Federation.

Company pays premium to bilingual employees

The Chemical Workers Union and the Utility Workers Union of America jointly negotiated a 2-year contract with

Southern California Gas Co. for 7,200 workers. The new agreement provides for a 4.5-percent wage increase effective April 1, 1986. On April 1, 1987, the workers will receive a 3.5-percent guaranteed increase and an additional possible increase of up to 2.5 percent, contingent on the movement of the Consumer Price Index.

A new provision the company characterized as unique to the industry provides for a 32-cent-an-hour premium for about 40 bilingual employees who answer telephone inquiries from persons who do not speak English.

In a cost-containment move, doctors planning to hospitalize an employee or dependent covered by the health insurance plan will have to clear the action with doctors hired by Southern California Gas. In other benefit changes, two free teeth cleanings per year were added to dental coverage and the amount of vacation time that can be carried over from year to year was increased to 3 weeks, from 2 weeks.

Philadelphia transit workers end strike

In the Philadelphia area, a 5-day transit strike ended when the Southeastern Pennsylvania Transportation Authority and the Transport Workers agreed on a contract.

"Harassment" by supervisors, the most significant issue from the workers' viewpoint, was dealt with by adoption of a provision requiring the Transit Authority to pay the cost of grievance arbitration proceedings in which the arbitrator rules in favor of the union. If the ruling favors management, the union pays the full cost. If there is no clear winner, the arbitration costs will be paid from a $50,000 a year fund that Philadelphia Mayor Wilson Goode promised to set up. Any unexpended portion of the annual allocation will be used to provide joint labor-management training for supervisors and stewards. Under the prior agreement, all arbitration costs were shared by the Transportation Authority and the Transport Workers.

According to a union official, the 5,100 members of the bargaining unit were involved in about 10,000 informal grievance filings per year, with about 1,200 of them ending as formal grievances and 120 going to arbitration.

The accord did not provide for a pay increase during the first year, but the employees will recieve four increases totaling $1 an hour during the balance of the 3-year term. Their pay, which reportedly averaged $11.12 an hour at the time of settlement, also will be subject to possible changes during the second and third years as a result of the continuation of the provision for cost-of-living pay adjustments.

The major change in benefits was liberalization of the pension formula for early retirement. Now, pensions will be reduced by 4 percent for each year an employee is under age 65 at retirement. Previously, the reduction factor was 6 percent.

Electric workers negotiate wage increase

On the East Coast, three unions negotiated 3-year agreements for 3,300 employees of the New England Electric System. The contracts, which contained similar terms, provided for wage increases of 4.3 percent in March 1986, 4.2 percent in March 1987, and 4.1 percent in March 1988.

The normal annual pension was raised to 1.8 percent (from 1.7 percent) of average annual earnings during the highest consecutive 5 years of the final 10 years of service, multiplied by years of service to a maximum of 30. Also, the early retirement age requirement was reduced to age 60, from 61.

Other terms included an increase in employer financing of health insurance and continuation of a program to contain premium costs; and a 5- to 12-cent-an-hour increase in shift premiums, varying by job category and union.

The three unions are the Brotherhood of Utility Workers of New England, representing 1,600 workers, the Utility Workers Union of America (525 workers), and the International Brotherhood of Electrical Workers (1,050 workers). New England Electric comprises Granite State Electric, Co., Massachusetts Electric Co., Narragansett Electric, New England Power Co., and New England Power Service. The companies provide electrical service in Massachusetts, New Hampshire, and Rhode Island.

Grocery clerks get five lump-sum payments

In Northern California, 40,000 grocery clerks were covered by a contract between several grocery store chains and 13 locals of the United Food and Commercial Workers. Over the 3-year term, employees will receive five lump-sum payments based on their hours worked (up to 40 hours per week) during the preceding 6 months. The first payment will be calculated at 25 cents for each hour worked during March 1 to August of 1986. The four succeeding payments will be calculated at 42 cents per hour worked by top-rated clerks, 28 cents for general merchandise clerks, and 20 cents for courtesy clerks. All five payments for courtesy clerks hired after the effective date of the contract will be calculated at 15 cents per hour worked.

On the last day of the contract, February 28, 1989, there will be a wage increase of 25 cents for general merchandise clerks, 30 cents for top-rate clerks, and 35 cents for head clerks.

The terms, which were similar to those negotiated by the union's meatcutters locals with the same companies in 1985, also include an $800,000 increase in major medical coverage (to $1 million) and a new individual retirement account plan supplementing the regular pension plan.

Spiegel contract contains 'no move' provision

About 2,800 catalogue sales employees in the Chicago area were covered by a settlement between Spiegel, Inc., and local 743 of the Teamsters union. General wage increases total $1.15 over the 3-year term, with 700 workers under the company's production bonus system being eligible to earn about a third more than $1.15.

Other terms included continuation of the provision for annual cost-of-living pay adjustments calculated at 1 cent an hour for each 0.4-point movement in the Consumer Price Index for the Chicago area; a $50 bonus for full-time employees and $25 for part-timers; a $2 increase in the pension rate to $10 a month for each year of credited service; and continuation of a "no-move" provision, requiring the company to operate the covered facilities until February 29, 1991.

Department store workers in DC area settle

In the Washington, DC–Baltimore, MD, area, 5,500 department store employees were covered by a settlement between Woodward & Lothrop, Inc., and the United Food and Commercial Workers. The 39-month contract, scheduled to run to May 1, 1989, provided for hourly paid employees to receive three wage increases over the term, each averaging about 5 percent. According to the company, the increases will range from 55 cents to $1.70 an hour, varying by job classification.

Rates were not changed for employees paid on a commission basis, but they received a lump-sum bonus equal to 1.5 percent of their 1985 earnings.

Benefit changes for all employees included a 5-percent increase in pension rates for past service and a 25- to 30-percent increase for future service; adoption of changes in the health insurance plan intended to slow the rise in costs; increases in sick leave pay; and increases in premium pay for Sunday work.

Minneapolis grocery workers get new contract

A wide-ranging 3-year contract between Minneapolis grocery chains and the United Food and Commercial Workers provided for a two-tier pay system for part-time workers, lump-sum payments for all 8,000 workers, a joint committee to consider the introduction of new meat department sales items, changes in job rules and duties, and additional employee protection against layoffs.

During the first contract year, the workers will not receive a pay increase, but in the second year they will receive a 3-percent increase, and in the final year will receive two lump-sum payments together equal to 3 percent of their earnings during a 12-month period. The pension rate was increased to $26.67 a month for each year of credited service (from $20) and the service requirement was changed to permit retirement after 30 years, regardless of age.

Part-time clerks and delicatessen workers hired after the March 1 effective date of the contract will start at $5 an hour, and advance to $8 after 5,200 hours of work. Part-time clerks hired earlier started at $5.76 and have a top rate of $9.38.

In a move to control labor costs, stores with three or fewer meatcutters will now be permitted to operate meat departments without a top-rated cutter present after 6 p.m. weekdays and all day on Sunday. Other efforts to control labor costs included establishment of a joint committee authorized to introduce new meat items during the contract term; a program for moderating increases in health insurance costs; and establishment of a "meat service" job category expanding the duties performed by a meat wrapper.

In return for these cost-cutting measures, the employers gave up the right to lay off employees hired after August 31, 1985, except in cases where they decide to close a store or can demonstrate a persistent and irreversible decline in sales.

Health care industry agreements

In Chicago, a settlement between Northwestern Memorial Hospital and the Hospital Employees Labor Program (HELP) increased the incentive for the 1,000 service and maintenance workers to use Northwestern when they are sick or injured. Under the 3-year contract, employees will not be required to pay any medical care costs incurred in Northwestern. If they use another hospital, they will have to pay the first $800 of costs and 20 percent of the balance. Under the prior contract, employees who used other hospitals were required to pay the first $50 of daily room and board for up to 6 days and the health care plan paid all additional costs.

Other terms included wage increases totaling 62 cents an hour that will reportedly raise average pay to $8.22; a $5 a month increase in single employees' financing of health benefits and a $10 increase for family coverage; and adoption of a two-tier pay system under which new employees will start at an average of $1.10 an hour below the top rate for their job and will receive regular progression increases, but will not attain the top rate during the agreement term.

HELP is a joint organization of Service Employees Local 73 and Teamsters Local 743.

Elsewhere in the health care industry, 2,500 doctors, dentists, optometrists, podiatrists, and veterinarians employed by the City of New York were covered by a 3-year contract that provided for a 5-percent salary increase retroactive to July 1, 1984, another 5-percent increase retroactive to July 1, 1985, and a 6-percent increase on July 1, 1986. This will bring the maximum annual salary to $88,807 for "attending III physicians" with at least 15 years of service. Previously, their maximum was $72,709.

The contract was negotiated by a Doctors Council and the city's Health and Hospitals Corporation.

New York State, University Professions settle

A round of bargaining between the State of New York and various unions was finally concluded when the United University Professions, an affiliate of the American Federation of Teachers, settled with the university system, ending an impasse of more than 8 months. The other unions had settled with various State agencies in 1985. (See *Monthly Labor Review*, October 1985, p. 52.)

The 3-year accord for the 17,000 academic and related professional employees provides for 5-percent wage increases in each contract year. The union also joined a new "preferred provider network" that went into operation on January 1, 1986, in an effort to contain rising health care costs.

Police officers get arbitrated pay increase

Police officers in Pittsburgh, PA, received a 4-percent immediate pay increase under a 2-year arbitration award. Resulting annual salaries included $25,792 for fourth-year officers, $28,288 for sergeants, $30,992 for lieutenants, and $34,112 for captains. There also is a provision for reopening the contract on wages in 1987.

Other terms for the 1,200 officers, represented by the Fraternal Order of Police, included longevity pay ranging from 2 percent of annual pay after 5 years' service to 8 percent after 35 years; a 10-percent pay differential between the ranks; a $4 a month city payment into the legal services fund (formerly $2); and a $5 a month increase in the city's payment into a supplemental pension fund, bringing the rates to $20 for each year of service for 20 through 24 years and to $25 for each additional year.

The award was handed down under a State law permitting arbitration when bargainers cannot reach an agreement. ☐

Those other workers

Migrant workers usually have less security of tenure than the local workers. If there are national economic difficulties, and workers have to be dismissed, the migrant workers are likely to have to return home. Their working conditions may be similar to those of others around them, but their housing and entitlement to social services are usually inferior. They are made aware daily that they are in a strange land, and enjoy few of the rights of a citizen.

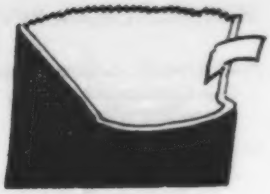
Book Reviews



A positive approach

Economic Statecraft. By David A. Baldwin. Princeton, NJ, Princeton University Press, 1985. 409 pp. $12.50 (US), paper.

David Baldwin's aggressively scholarly book should become required reading for anyone making a serious study of economics as an instrument of international politics. Baldwin cites three main purposes in writing this book: (1) to submit the conventional wisdom—that economic instruments are poor instruments of statecraft—to critical review; (2) to stimulate increased awareness of the many forms of economic statecraft; and (3) to develop an analytical framework within which the utility of economic instruments of policy can be discussed. Baldwin is successful to varying degrees at each of these tasks, but it is his excellent handling of the first that makes the book.

The conventional wisdom holds that "economic boycotts never work," "economic 'sticks' do not increase leverage and control over another nation," "sanctions end up making the target country more self-sufficient and strengthening its resolve to continue its policies." These statements are so categorical that one's first suspicion is that they must be, at the very least, overstatements. Indeed, Baldwin's secondary research indicates that close examination of existing case studies finds conflicting evaluations of the efficacy of economic statecraft. His reexamination of several cases widely cited in support of the conventional wisdom convinces the reader that even these "classic" cases are not the definitive evidence against economic statecraft they purport to be. The widely cited "failures" often reflect the analyst's evaluation of the ends of a particular policy, with the specific instruments of that policy fallaciously branded as "ineffective." Baldwin dismisses this confusion of ends and means with the disdain such errors deserve. The perception of policy failure may also reflect an expectation that a narrow economic tool—usually a trade embargo—can be used to effect profound changes in the internal and external behavior of states. Baldwin extends the concept of economic statecraft to include a wider variety of sanctions and rewards and with respect to the conventional literature's preoccupation with single, sweeping goals, reminds the reader that "a given influence attempt may involve multiple goals and targets of varying generality and significance."

Baldwin's third objective, introduction of the basic methods of social power analysis to the study of instruments of statecraft, is attempted in the second chapter. This is one of the weaker points in this work. I did not feel I came away from this chapter well enough briefed on "modern social power analysis" to meaningfully distinguish it from the simple application of generic critical analysis to the field of economic statecraft.

In the end, Baldwin's point is that economic statecraft is a far subtler discipline than the conventional, oversimplified cases suggest. Rather than ask, did a boycott get Castro to step down, or did an embargo drive Israel to abolish itself, a foreign policy analyst might have to be content asking if costs were imposed by one nation for another's noncompliance with relatively modest policy goals. The important question is whether foreign policy is well served by economic instruments in an environment where, as Baldwin sums up, "targets and goals are usually multiple," "success is usually a matter of degree," "alternatives matter," and "the bases of power are many and varied." Given that the most frequently cited alternatives to economic instruments are military adventures, every serious foreign policy analyst should read *Economic Statecraft*.

NOTES ON CURRENT LABOR STATISTICS

This section of the *Review* presents the principal statistical series collected and calculated by the Bureau of Labor Statistics: series on labor force, employment, unemployment, collective bargaining settlements, consumer, producer, and international prices, productivity, international comparisons, and injury and illness statistics. In the notes that follow, the data in each group of tables is briefly described, key definitions are given, notes on the data are set forth, and sources of additional information are cited.

General notes

The following notes apply to several tables in this section:

Seasonal adjustment. Certain monthly and quarterly data are adjusted to eliminate the effect on the data of such factors as climatic conditions, industry production schedules, opening and closing of schools, holiday buying periods, and vacation practices, which might prevent short-term evaluation of the statistical series. Tables containing data that have been adjusted are identified as "seasonally adjusted." (All other data are not seasonally adjusted.) Seasonal effects are estimated on the basis of past experience. When new seasonal factors are computed each year, revisions may affect seasonally adjusted data for several preceding years. (Seasonally adjusted data appear in tables 1–3, 4–10, 13, 14, and 18.) Beginning in January 1980, the BLS introduced two major modifications in the seasonal adjustment methodology for labor force data. First, the data are being seasonally adjusted with a new procedure called X–11 ARIMA, which was developed at Statistics Canada as an extension of the standard X–11 method previously used by BLS. A detailed description of the procedure appears in *The X–11 ARIMA Seasonal Adjustment Method* by Estla Bee Dagum (Statistics Canada, Catalogue No. 12–564E, January 1983). The second change is that seasonal factors are now being calculated for use during the first 6 months of the year, rather than for the entire year, and then are calculated at mid-year for the July-December period. However, revisions of historical data continue to be made only at the end of each calendar year.

Seasonally adjusted labor force data in tables 1 and 4–10 were revised in the February 1986 issue of the *Review*, to reflect experience through 1985.

Annual revisions of the seasonally adjusted payroll data shown in tables 13, 14, and 18 were made in July 1985 using the X–11 ARIMA seasonal adjustment methodology. New seasonal factors for productivity data in table 42 are usually introduced in the September issue. Seasonally adjusted indexes and percent changes from month to month and from quarter to quarter are published for numerous Consumer and Producer Price Index series. However, seasonally adjusted indexes are not published for the U.S. average All Items CPI. Only seasonally adjusted percent changes are available for this series.

Adjustments for price changes. Some data—such as the Hourly Earnings Index in table 17—are adjusted to eliminate the effect of changes in price. These adjustments are made by dividing current dollar values by the Consumer Price Index or the appropriate component of the index, then multiplying by 100. For example, given a current hourly wage rate of $3 and a current price index number of 150, where 1967 = 100, the hourly rate expressed in 1967 dollars is $2 ($3/150 × 100 = $2). The $2 (or any other resulting values) are described as "real," "constant," or "1967" dollars.

Additional information

Data that supplement the tables in this section are published by the Bureau in a variety of sources. Press releases provide the latest statistical information published by the Bureau; the major recurring releases are published according to the schedule preceding these general notes. More information about labor force, employment, and unemployment data and the household and establishment surveys underlying the data are available in *Employment and Earnings*, a monthly publication of the Bureau. More data from the household survey is published in the two-volume data book—*Labor Force Statistics Derived From the Current Population Survey*, Bulletin 2096. More data from the establishment survey appears in two data books—*Employment, Hours, and Earnings, United States*, and *Employment, Hours, and Earnings, States and Areas*, and the annual supplements to these data books. More detailed information on employee compensation and collective bargaining settlements is published in the monthly periodical, *Current Wage Developments*. More detailed data on consumer and producer prices are published in the monthly periodicals, *The CPI Detailed Report*, and *Producer Prices and Price Indexes*. Detailed data on all of the series in this section are provided in the *Handbook of Labor Statistics*, which is published biennally by the Bureau. BLS bulletins are issued covering productivity, injury and illness, and other data in this section. Finally, the *Monthly Labor Review* carries analytical articles on annual and longer term developments in labor force, employment and unemployment; employee compensation and collective bargaining; prices; productivity; international comparisons; and injury and illness data.

Symbols

p = preliminary. To increase the timeliness of some series, preliminary figures are issued based on representative but incomplete returns.
r = revised. Generally, this revision reflects the availability of later data but may also reflect other adjustments.
n.e.c. = not elsewhere classified.
n.e.s. = not elsewhere specified.

COMPARATIVE INDICATORS
(Tables 1–3)

Comparative indicators tables provide an overview and comparison of major BLS statistical series. Consequently, although many of the included series are available monthly, all measures in these comparative tables are presented quarterly and annually.

Labor market indicators include employment measures from two major surveys and information on rates of change in compensation provided by the Employment Cost Index (ECI) program. The labor force participation rate, the employment-to-population ratio, and unemployment rates for major demographic groups based on the Current Population ("household") Survey are presented, while measures of employment and average weekly hours by major industry sector are given using nonagricultural payroll data. The Employment Cost Index (compensation), by major sector and by bargaining status, is chosen from a variety of BLS compensation and wage measures because it provides a comprehensive measure of employer costs for hiring labor, not just outlays for wages, and it is not affected by employment shifts among occupations and industries.

Data on **changes in compensation, prices, and productivity** are presented in table 2. Measures of rates of change of compensation and wages from the Employment Cost Index program are provided for all civilian

nonfarm workers (excluding Federal and household workers) and for all private nonfarm workers. Measures of changes in: consumer prices for all urban consumers; producer prices by stage of processing; and the overall export and import price indexes are given. Measures of productivity (output per hour of all persons) are provided for major sectors.

Alternative measures of wage and compensation rates of change, which reflect the overall trend in labor costs, are summarized in table 3. Differences in concepts and scope, related to the specific purposes of the series, contribute to the variation in changes among the individual measures.

Notes on the data

Definitions of each series and notes on the data are contained in later sections of these notes describing each set of data. For detailed descriptions of each data series, see *BLS Handbook of Methods*, Volumes I and II, Bulletins 2134–1 and 2134–2 (Bureau of Labor Statistics, 1982 and 1984, respectively), as well as the additional bulletins, articles, and other publications noted in the separate sections of the *Review*'s "Current Labor Statistics Notes." Historical data for many series are provided in the *Handbook of Labor Statistics, Bulletin 2217* (Bureau of Labor Statistics, 1985). Users may also wish to consult *Major Programs, Bureau of Labor Statistics*, Report 718 (Bureau of Labor Statistics, 1985).

EMPLOYMENT DATA

(Tables 1; 4–21)

Household survey data

Description of the series

EMPLOYMENT DATA in this section are obtained from the Current Population Survey, a program of personal interviews conducted monthly by the Bureau of the Census for the Bureau of Labor Statistics. The sample consists of about 59,500 households selected to represent the U.S. population 16 years of age and older. Households are interviewed on a rotating basis, so that three-fourths of the sample is the same for any 2 consecutive months.

Definitions

Employed persons include (1) all civilians who worked for pay any time during the week which includes the 12th day of the month or who worked unpaid for 15 hours or more in a family-operated enterprise and (2) those who were temporarily absent from their regular jobs because of illness, vacation, industrial dispute, or similar reasons. Members of the Armed Forces stationed in the United States are also included in the employed total. A person working at more than one job is counted only in the job at which he or she worked the greatest number of hours.

Unemployed persons are those who did not work during the survey week, but were available for work except for temporary illness and had looked for jobs within the preceding 4 weeks. Persons who did not look for work because they were on layoff or waiting to start new jobs within the next 30 days are also counted among the unemployed. The **overall unemployment rate** represents the number unemployed as a percent of the labor force, including the resident Armed Forces. The **civilian unemployment rate** represents the number unemployed as a percent of the civilian labor force.

The **labor force** consists of all employed or unemployed civilians plus members of the Armed Forces stationed in the United States. Persons **not in the labor force** are those not classified as employed or unemployed; this group includes persons who are retired, those engaged in their own housework, those not working while attending school, those unable to work because of long-term illness, those discouraged from seeking work because of personal or job market factors, and those who are voluntarily idle. The **noninstitutional population** comprises all persons 16 years of age and older who are not inmates of penal or mental institutions, sanitariums, or homes for the aged, infirm, or needy, and members of the Armed Forces stationed in the United States. The **labor force participation rate** is the proportion of the noninstitutional populaton that is in the labor force. The **employment-population ratio** is total employment (including the resident Armed Forces) as a percent of the noninstitutional population.

Notes on the data

From time to time, and especially after a decennial census, adjustments are made in the Current Population Survey figures to correct for estimating errors during the preceding years. These adjustments affect the comparability of historical data. A description of these adjustments and their effect on the various data series appear in the Explanatory Notes of *Employment and Earnings*.

Data in tables 4–10 are seasonally adjusted, based on the seasonal experience through December 1984.

Additional sources of information

For detailed explanations of the data, see *BLS Handbook of Methods*, Bulletin 2134–1 (Bureau of Labor Statistics, 1982), chapter 1, and for additional data, *Handbook of Labor Statistics*, Bulletin 2217 (Bureau of Labor Statistics, 1985). A detailed description of the Current Population Survey as well as additional data are available in the monthly Bureau of Labor Statistics periodical, *Employment and Earnings*. Historical data from 1948 to 1982 are available in *Labor Force Statistics Derived from the Current Population Survey: A Databook*, Vols. I and II, Bulletin 2096 (Bureau of Labor Statistics, 1982).

A comprehensive discussion of the differences between household and establishment data on employment appears in Gloria P. Green, "Comparing employment estimates from household and payroll surveys," *Monthly Labor Review*, December 1969, pp. 9–20.

Establishment survey data

Description of the series

EMPLOYMENT, HOURS, AND EARNINGS DATA in this section are compiled from payroll records reported monthly on a voluntary basis to the Bureau of Labor Statistics and its cooperating State agencies by more than 200,000 establishments representing all industries except agriculture. In most industries, the sampling probabilities are based on the size of the establishment; most large establishments are therefore in the sample. (An establishment is not necessarily a firm; it may be a branch plant, for example, or warehouse.) Self-employed persons and others not on a regular civilian payroll are outside the scope of the survey because they are excluded from establishment records. This largely accounts for the difference in employment figures between the household and establishment surveys.

Definitions

An **establishment** is an economic unit which produces goods or services (such as a factory or store) at a single location and is engaged in one type of economic activity.

Employed persons are all persons who received pay (including holiday

and sick pay) for any part of the payroll period including the 12th of the month. Persons holding more than one job (about 5 percent of all persons in the labor force) are counted in each establishment which reports them.

Production workers in manufacturing include blue-collar worker supervisors and all nonsupervisory workers closely associated with production operations. Those workers mentioned in tables 12–16 include production workers in manufacturing and mining; construction workers in construction; and nonsupervisory workers in the following industries: transportation and public utilities; wholesale and retail trade; finance, insurance, and real estate; and services. These groups account for about four-fifths of the total employment on private nonagricutural payrolls.

Earnings are the payments production or nonsupervisory workers receive during the survey period, including premium pay for overtime or late-shift work but excluding irregular bonuses and other special payments. **Real earnings** are earnings adjusted to reflect the effects of changes in consumer prices. The deflator for this series is derived from the Consumer Price Index for Urban Wage Earners and Clerical Workers (CPI-W). The **Hourly Earnings Index** is calculated from average hourly earnings data adjusted to exclude the effects of two types of changes that are unrelated to underlying wage-rate developments: fluctuations in overtime premiums in manufacturing (the only sector for which overtime data are available) and the effects of changes and seasonal factors in the proportion of workers in high-wage and low-wage industries.

Hours represent the average weekly hours of production or nonsupervisory workers for which pay was received and are different from standard or scheduled hours. **Overtime hours** represent the portion of gross average weekly hours which were in excess of regular hours and for which overtime premiums were paid.

The Diffusion Index, introduced in the May 1983 *Review*, represents the percent of 185 nonagricultural industries in which employment was rising over the indicated period. One-half of the industries with unchanged employment are counted as rising. In line with Bureau practice, data for the 1-, 3-, and 6-month spans are seasonally adjusted, while those for the 12-month span are unadjusted. The diffusion index is useful for measuring the dispersion of economic gains or losses and is also an economic indicator.

Notes on the data

Establishment data collected by the Bureau of Labor Statistics are periodically adjusted to comprehensive counts of employment (called "benchmarks"). The latest complete adjustment was made with the release of May 1985 data, published in the July 1985 issue of the *Review*. Consequently, data published in the *Review* prior to that issue are not necessarily comparable to current data. Unadjusted data have been revised back to April 1983; seasonally adjusted data have been revised back to January 1980. These revisions were published in the *Supplement to Employment and Earnings* (Bureau of Labor Statistics, 1985). Unadjusted data from April 1984 forward, and seasonally adjusted data from January 1981 forward are subject to revision in future benchmarks.

Additional sources of information

Detailed data from the establishment survey are published monthly in the BLS periodical, *Employment and Earnings*. Earlier comparable unadjusted and seasonally adjusted data are published in *Employment, Hours, and Earnings, United States, 1909–84*, Bulletin 1312–12 (Bureau of Labor Statistics, 1985) and its annual supplement. For a detailed discussion of the methodology of the survey, see *BLS Handbook of Methods*, Bulletin 2134–1 (Bureau of Labor Statistics, 1982), chapter 2. For additional data, see *Handbook of Labor Statistics*, Bulletin 2217 (Bureau of Labor Statistics, 1985).

A comprehensive discussion of the differences between household and establishment data on employment appears in Gloria P. Green, "Comparing employment estimates from household and payroll surveys," *Monthly Labor Review*, December 1969, pp. 9–20.

Unemployment data by State

Description of the series

Data presented in this section are obtained from two major sources—the Current Population Survey (CPS) and the Local Area Unemployment Statistics (LAUS) program, which is conducted in cooperation with State employment security agencies.

Monthly estimates of the labor force, employment, and unemployment for States and sub-State areas are a key indicator of local economic conditions and form the basis for determining the eligibility of an area for benefits under Federal economic assistance programs such as the Job Training Partnership Act and the Public Works and Economic Development Act. Insofar as possible, the concepts and definitions underlying these data are those used in the national estimates obtained from the CPS.

Notes on the data

Data refer to State of residence. Monthly data for 11 States—California, Florida, Illinois, Massachusetts, Michigan, New York, New Jersey, North Carolina, Ohio, Pennsylvania, and Texas—are obtained directly from the CPS, because the size of the sample is large enough to meet BLS standards of reliability. Data for the remaining 39 States and the District of Columbia are derived using standardized procedures established by BLS. Once a year, estimates for the 11 States are revised to new population controls. For the remaining States and the District of Columbia, data are benchmarked to annual average CPS levels.

Additional sources of information

Information on the concepts, definitions, and technical procedures used to develop labor force data for States and sub-State areas as well as additional data on sub-States are provided in the monthly Bureau of Labor Statistics periodical, *Employment and Earnings*, and the annual report, *Geographic Profile of Employment and Unemployment* (Bureau of Labor Statistics). See also *BLS Handbook of Methods*, Bulletin 2134–1 (Bureau of Labor Statistics, 1982), chapter 4.

COMPENSATION AND WAGE DATA

(Tables 1–3; 22–29)

COMPENSATION AND WAGE DATA are gathered by the Bureau from business establishments, State and local governments, labor unions, collective bargaining agreements on file with the Bureau, and secondary sources.

Employment Cost Index

Description of the series

The **Employment Cost Index** (ECI) is a quarterly measure of the rate of change in compensation per hour worked and includes wages, salaries, and employer costs of employee benefits. It uses a fixed market basket of labor—similar in concept to the Consumer Price Index's fixed market basket of goods and services—to measure change over time in employer costs of employing labor. The index is not seasonally adjusted.

Statistical series on total compensation costs and on wages and salaries are available for private nonfarm workers excluding proprietors, the self-employed, and household workers. Both series are also available for State and local government workers and for the civilian nonfarm economy, which consists of private industry and State and local government workers combined. Federal workers are excluded.

The Employment Cost Index probability sample consists of about 2,200 private nonfarm establishments providing about 12,000 occupational observations and 700 State and local government establishments providing

3,500 occupational observations selected to represent total employment in each sector. On average, each reporting unit provides wage and compensation information on five well-specified occupations. Data are collected each quarter for the pay period including the 12th day of March, June, September, and December.

Fixed employment weights from the 1970 Census of Population are used each quarter to calculate the indexes for civilian, private, and State and local governments. These fixed weights, also used to derive all of the industry and occupation series indexes, ensure that changes in these indexes reflect only changes in compensation, not employment shifts among industries or occupations with different levels of wages and compensation. For the bargaining status, region, and metropolitan/nonmetropolitan area series, however, employment data by industry and occupation are not available from the census. Instead, the 1970 employment weights are reallocated within these series each quarter based on the current sample. Therefore, these indexes are not strictly comparable to those for the aggregate, industry, and occupation series.

Definitions

Total compensation costs include wages, salaries, and the employer costs for employee benefits.

Wages and salaries consist of earnings before payroll deductions, including production bonuses, incentive earnings, commissions, and cost-of-living adjustments.

Benefits include the cost to employers for paid leave, supplemental pay (including nonproduction bonuses), insurance, retirement and savings plans, and legally required benefits (such as social security, workers' compensation, and unemployment insurance).

Excluded from wages and salaries and employee benefits are such items as payment-in-kind, free room and board, and tips.

Notes on the data

The Employment Cost Index data series began in the fourth quarter of 1975, with the quarterly percent change in wages and salaries in the private nonfarm sector. Data on employer costs for employee benefits were included in 1980 to produce, when combined with the wages and salaries series, a measure of the percent change in employer costs for employee total compensation. State and local government units were added to the ECI coverage in 1981, providing a measure of total compensation change in the *civilian* nonfarm economy (excluding Federal employees). Historical indexes (June 1981 = 100) of the quarterly rates of change are presented in the May issue of the BLS monthly periodical, *Current Wage Developments*.

Additional sources of information

For a more detailed discussion of the Employment Cost Index, see Chapter 11, "The Employment Cost Index," in the *Handbook of Methods*, Bulletin 2134–1 (Bureau of Labor Statistics, 1982), and the following *Monthly Labor Review* articles: "Employment Cost Index: a measure of change in the 'price of labor'," July 1975; "How benefits will be incorporated into the Employment Cost Index," January 1978; "Estimation procedures for the Employment Cost Index," May 1982; and "Introducing new weights for the Employment Cost Index," June 1985.

Data on the ECI are also available in BLS quarterly press releases issued in the month following the reference months of March, June, September, and December; and from the *Handbook of Labor Statistics*, Bulletin 2217 (Bureau of Labor Statistics, 1985).

Collective bargaining settlements

Description of the series

Collective bargaining settlements data provide statistical measures of negotiated adjustments (increases, decreases, and freezes) in compensation (wages and benefits costs) and wages alone, quarterly for private industry and semiannually for State and local government. Compensation measures cover all collective bargaining situations involving 5,000 workers or more and wage measures cover all situations involving 1,000 workers or more. These data, covering private nonagricultural industries and State and local governments, are calculated using information obtained from bargaining agreements on file with the Bureau, parties to the agreements, and secondary sources, such as newspaper accounts. The data are not seasonally adjusted.

Settlement data are measured in terms of future specified adjustments: those that will occur within 12 months after contract ratification—first year—and all adjustments that will occur over the life of the contract expressed as an average annual rate. Adjustments are worker weighted. Both first-year and over-the-life measures exclude wage changes that may occur under cost-of-living clauses that are triggered by future movements in the Consumer Price Index.

Effective wage adjustments measure all adjustments occurring in the reference period, regardless of the settlement date. Included are changes from settlements reached during the period, changes deferred from contracts negotiated in earlier periods, and changes under cost-of-living adjustment clauses. Each wage change is worker weighted. The changes are prorated over all workers under agreements during the reference period yielding the average adjustment.

Definitions

Wage rate changes are calculated by dividing newly negotiated wages by the average hourly earnings, excluding overtime, at the time the agreement is reached. Compensation changes are calculated by dividing the change in the value of the newly negotiated wage and benefit package by existing average hourly compensation, which includes the cost of previously negotiated benefits, legally required social insurance programs, and average hourly earnings.

Compensation changes are calculated by placing a value on the benefit portion of the settlements at the time they are reached. The cost estimates are based on the assumption that conditions existing at the time of settlement (for example, methods of financing pensions or composition of labor force) will remain constant. The data, therefore, are measures of negotiated changes and not of total changes in employer cost.

Contract duration runs from the effective date of the agreement to the expiration date or first wage reopening date, if applicable. Average annual percent changes over the contract term take account of the compounding of successive changes.

Notes on the data

Care should be exercised in comparing the size and nature of the settlements in State and local government with those in the private sector because of differences in bargaining practices and settlement characteristics. A principal difference is the incidence of cost-of-living adjustment (COLA) clauses which cover only about 2 percent of workers under a few local government settlements, but cover 50 percent of workers under private sector settlements. Agreements without COLA's tend to provide larger specified wage increases than those with COLA's. Another difference is that State and local government bargaining frequently excludes pension benefits which are often prescribed by law. In the private sector, in contrast, pensions are typically a bargaining issue.

Additional sources of information

For a more detailed discussion on the series, see of the *BLS Handbook of Methods*, Bulletin 2134–1 (Bureau of Labor Statistics, 1982), chapter 10. Comprehensive data are published in press releases issued quarterly (in January, April, July, and October) for private industry, and semi-

annually (in February and August) for State and local government. Historical data and additional detailed tabulations for the prior calendar year appear in the April issue of the BLS monthly periodical, *Current Wage Developments*.

Work stoppages

Description of the series

Data on **work stoppages** measure the number and duration of major strikes or lockouts (involving 1,000 workers or more) occurring during the month (or year), the number of workers involved, and the amount of time lost because of stoppage.

Data are largely from newspaper accounts and cover only establishments directly involved in a stoppage. They do not measure the indirect or secondary effect of stoppages on other establishments whose employees are idle owing to material shortages or lack of service.

Definitions

Number of stoppages: The number of strikes and lockouts involving 1,000 workers or more and lasting a full shift or longer.

Workers involved: The number of workers directly involved in the stoppage.

Number of days idle: The aggregate number of work days lost by workers involved in the stoppages.

Days of idleness as a percent of estimated working time: Aggregate work days lost as a percent of the aggregate number of standard work days in the period multiplied by total employment in the period.

Notes on the data

This series is not comparable with the one terminated in 1981 that covered strikes involving six workers or more.

Additional sources of information

Data for each calendar year are reported in a BLS press release issued in the first quarter of the following year. Monthly data appear in the BLS monthly periodical, *Current Wage Developments*. Historical data appear in the BLS *Handbook of Labor Statistics*.

Other compensation data

Other BLS data on pay and benefits, not included in the Current Labor Statistics section of the *Monthly Labor Review*, appear in and consist of the following:

Industry Wage Surveys provide data for specific occupations selected to represent an industry's wage structure and the types of activities performed by its workers. The Bureau collects information on weekly work schedules, shift operations and pay differentials, paid holiday and vacation practices, and information on incidence of health, insurance, and retirement plans. Reports are issued throughout the year as the surveys are completed. Summaries of the data and special analyses also appear in the *Monthly Labor Review*.

Area Wage Surveys annually provide data for selected office, clerical, professional, technical, maintenance, toolroom, powerplant, material movement, and custodial occupations common to a wide variety of industries in the areas (labor markets) surveyed. Reports are issued throughout the year as the surveys are completed. Summaries of the data and special analyses also appear in the *Review*.

The National Survey of Professional, Administrative, Technical, and Clerical Pay provides detailed information annually on salary levels and distributions for the types of jobs mentioned in the survey's title in private employment. Although the definitions of the jobs surveyed reflect the duties and responsibilities in private industry, they are designed to match specific pay grades of Federal white-collar employees under the General Schedule pay system. Accordingly, this survey provides the legally required information for comparing the pay of salaried employees in the Federal civil service with pay in private industry. (See Federal Pay Comparability Act of 1970, 5 U.S.C. 5305.) Data are published in a BLS news release issued in the summer and in a bulletin each fall; summaries and analytical articles also appear in the *Review*.

Employee Benefits Survey provides nationwide information on the incidence and characteristics of employee benefit plans in medium and large establishments in the United States, excluding Alaska and Hawaii. Data are published in an annual BLS news release and bulletin, as well as in special articles appearing in the *Review*.

PRICE DATA
(Tables 2; 30–41)

PRICE DATA are gathered by the Bureau of Labor Statistics from retail and primary markets in the United States. Price indexes are given in relation to a base period (1967 = 100, unless otherwise noted).

Consumer Price Indexes

Description of the series

The **Consumer Price Index** (CPI) is a measure of the average change in the prices paid by urban consumers for a fixed market basket of goods and services. The CPI is calculated monthly for two population groups, one consisting only of urban households whose primary source of income is derived from the employment of wage earners and clerical workers, and the other consisting of all urban households. The wage earner index (CPI-W) is a continuation of the historic index that was introduced well over a half-century ago for use in wage negotiations. As new uses were developed for the CPI in recent years, the need for a broader and more representative index became apparent. The all urban consumer index (CPI-U) introduced in 1978 is representative of the 1972–73 buying habits of about 80 percent of the noninstitutional population of the United States at that time, compared with 40 percent represented in the CPI-W. In addition to wage earners and clerical workers, the CPI-U covers professional, managerial, and technical workers, the self-employed, short-term workers, the unemployed, retirees, and others not in the labor force.

The CPI is based on prices of food, clothing, shelter, fuel, drugs, transportation fares, doctors' and dentists' fees, and other goods and services that people buy for day-to-day living. The quantity and quality of these items are kept essentially unchanged between major revisions so that only price changes will be measured. All taxes directly associated with the purchase and use of items are included in the index.

Data collected from more than 24,000 retail establishments and 24,000 tenants in 85 urban areas across the country are used to develop the "U.S. city average." Separate estimates for 28 major urban centers are presented in table 31. The areas listed are as indicated in footnote 1 to the table. The area indexes measure only the average change in prices for each area since the base period, and do not indicate differences in the level of prices among cities.

Notes on the data

In January 1983, the Bureau changed the way in which homeownership costs are measured for the CPI-U. A rental equivalence method replaced the

asset-price approach to homeownership costs for that series. In January 1985, the same change was made in the CPI-W. The central purpose of the change was to separate shelter costs from the investment component of homeownership so that the index would reflect only the cost of shelter services provided by owner-occupied homes.

Additional sources of information

For a discussion of the general method for computing the CPI, see *BLS Handbook of Methods, Volume II, The Consumer Price Index*, Bulletin 2134–2 (Bureau of Labor Statistics, 1984). The recent change in the measurement of homeownership costs is discussed in Robert Gillingham and Walter Lane, "Changing the treatment of shelter costs for homeowners in the CPI," *Monthly Labor Review*, June 1982, pp. 9–14.

Additional detailed CPI data and regular analyses of consumer price changes are provided in the *CPI Detailed Report*, a monthly publication of the Bureau. Historical data for the overall CPI and for selected groupings may be found in the *Handbook of Labor Statistics*, Bulletin 2217 (Bureau of Labor Statistics, 1985).

Producer price indexes

Description of the series

Producer Price Indexes (PPI) measure average changes in prices received in primary markets of the United States by producers of commodities in all stages of processing. The sample used for calculating these indexes currently contains about 3,200 commodities and about 60,000 quotations per month selected to represent the movement of prices of all commodities produced in the manufacturing, agriculture, forestry, fishing, mining, gas and electricity, and public utilities sectors. The stage of processing structure of Producer Price Indexes organizes products by class of buyer and degree of fabrication (that is, finished goods, intermediate goods, and crude materials). The traditional commodity structure of PPI organizes products by similarity of end-use or material composition.

To the extent possible, prices used in calculating Producer Price Indexes apply to the first significant commercial transaction in the United States from the production or central marketing point. Price data are generally collected monthly, primarily by mail questionnaire. Most prices are obtained directly from producing companies on a voluntary and confidential basis. Prices generally are reported for the Tuesday of the week containing the 13th day of the month.

Since January 1976, price changes for the various commodities have been averaged together with implicit quantity weights representing their importance in the total net selling value of all commodities as of 1972. The detailed data are aggregated to obtain indexes for stage-of-processing groupings, commodity groupings, durability-of-product groupings, and a number of special composite groups. All Producer Price Index data are subject to revision 4 months after original publication.

Notes on the data

Beginning with the January 1986 issue, the *Review* is no longer presenting tables of Producer Price Indexes for commodity groupings, special composite groups, or SIC industries. However, these data will continue to be presented in the Bureau's monthly publication *Producer Price Indexes*.

The Bureau has completed the first major stage of its comprehensive overhaul of the theory, methods, and procedures used to construct the Producer Price Indexes. Changes include the replacement of judgment sampling with probability sampling techniques; expansion to systematic coverage of the net output of virtually all industries in the mining and manufacturing sectors; a shift from a commodity to an industry orientation; the exclusion of imports from, and the inclusion of exports in, the survey universe; and the respecification of commodities priced to conform to Bureau of the Census definitions. These and other changes have been phased in gradually since 1978. The result is a system of indexes that is easier to use in conjunction with data on wages, productivity, and employment and other series that are organized in terms of the Standard Industrial Classification and the Census product class designations.

Additional sources of information

For a discussion of the methodology for computing Producer Price Indexes, see *BLS Handbook of Methods*, Bulletin 2134–1 (Bureau of Labor Statistics, 1982), chapter 7.

Additional detailed data and analyses of price changes are provided monthly in *Producer Price Indexes*. Selected historical data may be found in the *Handbook of Labor Statistics*, Bulletin 2217 (Bureau of Labor Statistics, 1985).

International price indexes

Description of the series

The BLS **International Price Program** produces quarterly export and import price indexes for nonmilitary goods traded between the United States and the rest of the world. The export price index provides a measure of price change for all products sold by U.S. residents to foreign buyers. ("Residents" is defined as in the national income accounts: it includes corporations, businesses, and individuals but does not require the organizations to be U.S. owned nor the individuals to have U.S. citizenship.) The import price index provides a measure of price change for goods purchased from other countries by U.S. residents. With publication of an all-import index in February 1983 and an all-export index in February 1984, all U.S. merchandise imports and exports now are represented in these indexes. The reference period for the indexes is 1977 = 100, unless otherwise indicated.

The product universe for both the import and export indexes includes raw materials, agricultural products, semifinished manufactures, and finished manufactures, including both capital and consumer goods. Price data for these items are collected quarterly by mail questionnaire. In nearly all cases, the data are collected directly from the exporter or importer, although in a few cases, prices are obtained from other sources.

To the extent possible, the data gathered refer to prices at the U.S. border for exports and at either the foreign border or the U.S. border for imports. For nearly all products, the prices refer to transactions completed during the first 2 weeks of the third month of each calendar quarter—March, June, September, and December. Survey respondents are asked to indicate all discounts, allowances, and rebates applicable to the reported prices, so that the price used in the calculation of the indexes is the actual price for which the product was bought or sold.

In addition to general indexes of prices for U.S. exports and imports, indexes are also published for detailed product categories of exports and imports. These categories are defined by the 4- and 5-digit level of detail of the Standard Industrial Trade Classification System (SITC). The calculation of indexes by SITC category facilitates the comparison of U.S. price trends and sector production with similar data for other countries. Detailed indexes are also computed and published on a Standard Industrial Classification (SIC-based) basis, as well as by end-use class.

Notes on the data

The export and import price indexes are weighted indexes of the Laspeyeres type. Price relatives are assigned equal importance within each weight category and are then aggregated to the SITC level. The values assigned to each weight category are based on trade value figures compiled

by the Bureau of the Census. The trade weights currently used to compute both indexes relate to 1980.

Because a price index depends on the same items being priced from period to period, it is necessary to recognize when a product's specifications or terms of transaction have been modified. For this reason, the Bureau's quarterly questionnaire requests detailed descriptions of the physical and functional characteristics of the products being priced, as well as information on the number of units bought or sold, discounts, credit terms, packaging, class of buyer or seller, and so forth. When there are changes in either the specifications or terms of transaction of a product, the dollar value of each change is deleted from the total price change to obtain the "pure" change. Once this value is determined, a linking procedure is employed which allows for the continued repricing of the item.

For the export price indexes, the preferred pricing basis is f.a.s. (free alongside ship) U.S. port of exportation. When firms report export prices f.o.b. (free on board), production point information is collected which enables the Bureau to calculate a shipment cost to the port of exportation. An attempt is made to collect two prices for imports. The first is the import price f.o.b. at the foreign port of exportation, which is consistent with the basis for valuation of imports in the national accounts. The second is the import price c.i.f. (cost, insurance, and freight) at the U.S. port of importation, which also includes the other costs associated with bringing the product to the U.S. border. It does not, however, include duty charges.

Additional sources of information

For a discussion of the general method of computing International Price Indexes, see *BLS Handbook of Methods*, Bulletin 2134–1 (Bureau of Labor Statistics, 1982), chapter 8.

Additional detailed data and analyses of international price developments are presented in the Bureau's quarterly publication *U.S. Import and Export Price Indexes* and in occasional *Monthly Labor Review* articles prepared by BLS analysts. Selected historical data may be found in the *Handbook of Labor Statistics*, Bulletin 2217 (Bureau of Labor Statistics, 1985).

PRODUCTIVITY DATA
(Tables 2; 42–47)

U. S. productivity and related data

Description of the series

The productivity measures relate real physical output to real input. As such, they encompass a family of measures which include single factor input measures, such as output per unit of labor input (output per hour) or output per unit of capital input, as well as measures of multifactor productivity (output per unit of labor and capital inputs combined). The Bureau indexes show the change in output relative to changes in the various inputs. The measures cover the business, nonfarm business, manufacturing, and nonfinancial corporate sectors.

Corresponding indexes of hourly compensation, unit labor costs, unit nonlabor payments, and prices are also provided.

Definitions

Output per hour of all persons (labor productivity) is the value of goods and services in constant prices produced per hour of labor input. **Output per unit of capital services** (capital productivity) is the value of goods and services in constant dollars produced per unit of capital services input.

Multifactor productivity is the ratio output per unit of labor and capital inputs combined. Changes in this measure reflect changes in a number of factors which affect the production process such as changes in technology, shifts in the composition of the labor force, changes in capacity utilization, research and development, skill and efforts of the work force, management, and so forth. Changes in the output per hour measures reflect the impact of these factors as well as the substitution of capital for labor.

Compensation per hour is the wages and salaries of employees plus employers' contributions for social insurance and private benefit plans, and the wages, salaries, and supplementary payments for the self-employed (except for nonfinancial corporations in which there are no self-employed)—the sum divided by hours paid for. **Real compensation per hour** is compensation per hour deflated by the change in the Consumer Price Index for All Urban Consumers.

Unit labor costs are the labor compensation costs expended in the production of a unit of output and are derived by dividing compensation by output. **Unit nonlabor payments** include profits, depreciation, interest, and indirect taxes per unit of output. They are computed by subtracting compensation of all persons from current dollar value of output and dividing by output. **Unit nonlabor costs** contain all the components of unit nonlabor payments *except* unit profits.

Unit profits include corporate profits and the value of inventory adjustments per unit of output.

Hours of all persons are the total hours paid of payroll workers, self-employed persons, and unpaid family workers.

Capital services is the flow of services from the capital stock used in production. It is developed from measures of the net stock of physical assets—equipment, structures, land, and inventories—weighted by rental prices for each type of asset.

Labor and capital inputs combined are derived by combining changes in labor and capital inputs with weights which represent each component's share of total output. The indexes for capital services and combined units of labor and capital are based on changing weights which are averages of the shares in the current and preceding year (the Tornquist index-number formula).

Notes on the data

Output measures for the business sector and the nonfarm businesss sector exclude the constant dollar value of owner-occupied housing, rest of world, households and institutions, and general government output from the constant dollar value of gross national product. The measures are derived from data supplied by the Bureau of Economic Analysis, U.S. Department of Commerce, and the Federal Reserve Board. Quarterly manufacturing output indexes are adjusted by the Bureau of Labor Statistics to annual estimates of output (gross product originating) from the Bureau of Economic Analysis. Compensation and hours data are developed from data of the Bureau of Labor Statistics and the Bureau of Economic Analysis.

The productivity and associated cost measures in tables 42–44 describe the relationship between output in real terms and the labor time and capital services involved in its production. They show the changes from period to period in the amount of goods and services produced per unit of input. Although these measures relate output to hours and capital services, they do not measure the contributions of labor, capital, or any other specific factor of production. Rather, they reflect the joint effect of many influences, including changes in technology; capital investment; level of output; utilization of capacity, energy, and materials; the organization of production; managerial skill; and the characteristics and efforts of the work force.

Additional sources of information

Descriptions of methodology underlying the measurement of output per hour and multifactor productivity are found in the *BLS Handbook of Methods*, Bulletin 2134–1 (Bureau of Labor Statistics, 1982), chapter 13. Historical data for selected industries are provided in the Bureau's *Handbook of Labor Statistics*, 1985, Bulletin 2217.

International comparisons

Description of the series

Comparative measures of labor force, employment, and unemployment (tables 45 and 46) are prepared regularly for the United States, Canada, Australia, Japan, France, Germany, Great Britain, Italy, the Netherlands, and Sweden. Unemployment rates, approximating U.S. concepts, are prepared monthly for most of the countries; the other measures, annually.

The Bureau of Labor Statistics also prepares international comparisons of manufacturing labor productivity and labor costs (table 47) that cover the United States and 11 foreign countries—those listed above plus Belgium and Norway. These measures are limited to trend comparisons; that is, intercountry series of changes over time, rather than level comparisons because reliable international comparisons of the levels of manufacturing are unavailable. The U.S. measures are described in the notes on U.S. productivity measurement; the measures for foreign countries are compiled from various national and international data sources.

Definitions

Output measures are constant value output (value added) from the national accounts of each country, except for those for Japan prior to 1970 and for the Netherlands for 1969 forward, which are indexes of industrial production. The national accounting methods for measuring real output differ considerably among the 12 countries, but the use of different procedures does not, in itself, connote lack of comparability—rather, it reflects differences among countries in the availability and reliability of underlying data series.

Hours and compensation measures refer to all employed persons including the self-employed in the United States and Canada, and to all wage and salary employees in the other countries. *Hours* refer to hours *paid* in the United States, hours *worked* in the other countries. *Compensation (labor costs)* includes not only all payments made directly to employees and employer expenditures for social insurance and private benefit plans, but changes in significant employment or payroll taxes that are not compensation to employees but are labor costs to employers (France, Sweden, and the United Kingdom). Self-employed workers are included in the U.S. and Canadian figures by assuming that their hourly compensation is equal to the average for wage and salary employees.

Notes on the data

The data for the foreign countries in tables 45 and 46 have been adjusted, where necessary, for greater comparability with U.S. definitions of employment and unemployment. The adjusted statistics have been adapted to the age at which compulsory schooling ends in each country. Therefore, the adjusted statistics relate to the civilian population age 16 and over in the United States, France, and Sweden, and from 1973 forward, Great Britain; 15 and over in Canada, Australia, Japan, Germany, and the Netherlands; and 14 and over in Italy. Prior to 1973, the data for Great Britain related to persons age 15 and over. The institutional population is included in the denominator of the labor force participation rates and employment-population ratios for Japan and Germany.

For most of the countries in table 47, the measures refer to total manufacturing as defined by the International Standard Industrial Classification. However, the measures for France (beginning 1959), Italy (beginning 1970), and the United Kingdom (beginning 1976) refer to manufacturing and mining less energy-related products. For all countries, manufacturing includes the activities of government enterprises.

In addition, for all countries, preliminary estimates for recent years are generally based on current indicators of manufacturing output, employment and hours, and hourly compensation until national accounts and other statistics used for the long-term measures become available.

Additional sources of information

For further information, see *International Comparisons of Unemployment*, Bulletin 1979 (Bureau of Labor Statistics, 1978), Appendix B and Supplements to Appendix B. Additional detail is also found in the *BLS Handbook of Methods*, Bulletin 2134–1 (Bureau of Labor Statistics, 1982), chapter 16. Additional international comparison statistics are available in the *Handbook of Labor Statistics*, Bulletin 2217 (Bureau of Labor Statistics, 1985). The most recent statistics are presented and analyzed annually in the *Monthly Labor Review*, typically in the December issue (for the previous year) and in February.

OCCUPATIONAL INJURY AND ILLNESS DATA

(Table 48)

Description of the series

The Annual Survey of Occupational Injuries and Illnesses is designed to collect data on injuries and illnesses based on records which employers in the following industries maintain under the Occupational Safety and Health Act of 1970: agriculture, forestry, and fishing; oil and gas extraction; construction; manufacturing; transportation and public utilities; wholesale and retail trade; finance, insurance, and real estate; and services. Excluded from the survey are self-employed individuals, farmers with fewer than 11 employees, employers regulated by other Federal safety and health laws, and Federal, State, and local government agencies.

Because the survey is a Federal–State cooperative program and the data must meet the needs of participating State agencies, an independent sample is selected for each State. The sample is selected to represent all private industries in the States and territories. The sample size for the survey is dependent upon (1) the characteristics for which estimates are needed; (2) the industries for which estimates are desired; (3) the characteristics of the population being sampled; (4) the target reliability of the estimates; and (5) the survey design employed.

While there are many characteristics upon which the sample design could be based, the total recorded case incidence rate is used because it is one of the most important characteristics and the least variable; therefore, it requires the smallest sample size.

The survey is based on stratified random sampling with a Neyman allocation and a ratio estimator. The characteristics used to stratify the establishments are the Standard Industrial Classification (SIC) code and size of employment.

Definitions

Recordable occupational injuries and illnesses are: (1) occupational deaths, regardless of the time between injury and death, or the length of the illness; or (2) nonfatal occupational illnesses; or (3) nonfatal occupational injuries which involve one or more of the following: loss of consciousness, restriction of work or motion, transfer to another job, or medical treatment (other than first aid).

Occupational injury is any injury such as a cut, fracture, sprain, amputation, and so forth, which results from a work accident or from exposure involving a single incident in the work environment.

Occupational illness is an abnormal condition or disorder, other than one resulting from an occupational injury, caused by exposure to environmental factors associated with employment. It includes acute and chronic illnesses or disease which may be caused by inhalation, absorption, ingestion, or direct contact.

Lost workday cases are cases which involve days away from work, or days of restricted work activity, or both.

Lost workday cases involving restricted work activity are those cases which result in restricted work activity only.

Lost workdays away from work are the number of workdays (consecutive or not) on which the employee would have worked but could not because of occupational injury or illness.

Lost workdays—restricted work activity are the number of workdays (consecutive or not) on which, because of injury or illness: (1) the employee was assigned to another job on a temporary basis; or (2) the employee worked at a permanent job less than full time; or (3) the employee worked at a permanently assigned job but could not perform all duties normally connected with it.

The number of days away from work or days of restricted work activity does not include the day of injury or onset of illness or any days on which the employee would not have worked even though able to work.

Incidence rates represent the number of injuries and/or illnesses or lost workdays per 100 full-time workers.

Notes on the data

Estimates are made for industries and employment-size classes and for severity classification: fatalities, lost workday cases, and nonfatal cases without lost workdays. Lost workday cases are separated into those where the employee would have worked but could not and those in which work activity was restricted. Estimates of the number of cases and the number of days lost are made for both categories.

Most of the estimates are in the form of incidence rates, defined as the number of injuries and illnesses, or lost workdays, per 100 full-time employees. For this purpose, 200,000 employee hours represent 100 employee years (2,000 hours per employee). Only a few of the available measures are included in the *Handbook of Labor Statistics*. Full detail is presented in the annual bulletin, *Occupational Injuries and Illnesses in the United States, by Industry*.

Comparable data for individual States are available from the BLS Office of Occupational Safety and Health Statistics.

Mining and railroad data are furnished to BLS by the Mine Safety and Health Administration and the Federal Railroad Administration, respectively. Data from these organizations are included in BLS and State publications. Federal employee experience is compiled and published by the Occupational Safety and Health Administration. Data on State and local government employees are collected by about half of the States and territories; these data are not compiled nationally.

Additional sources of information

The Supplementary Data System provides detailed information describing various factors associated with work-related injuries and illnesses. These data are obtained from information reported by *employers* to State workers' compensation agencies. The Work Injury Report program examines selected types of accidents through an employee survey which focuses on the circumstances surrounding the injury. These data are not included in the *Handbook of Labor Statistics* but are available from the BLS Office of Occupational Safety and Health Statistics.

The definitions of occupational injuries and illnesses and lost workdays are from *Recordkeeping Requirements under the Occupational Safety and Health Act of 1970*. For additional data, see *Occupational Injuries and Illnesses in the United States, by Industry*, annual Bureau of Labor Statistics bulletin; BLS *Handbook of Methods*, Bulletin 2134–1 (Bureau of Labor Statistics, 1982), chapter 17; *Handbook of Labor Statistics*, Bulletin 2217 (Bureau of Labor Statistics, 1985), pp. 411–14; annual reports in the *Monthly Labor Review*; and annual U.S. Department of Labor press releases.

---

[1] Cost (cents-per-hour worked) measured in the Employment Cost Index consists of wages, salaries and employer cost of employee benefits.

[2] Consist of private industry workers (excluding farm and household workers) and State and local government (excluding Federal Government) workers.

[3] Consists of legislative, judicial, administrative, and regulatory activities.

[4] Includes, for example, library, social, and health services.

23. Employment Cost Index, wages and salaries, by occupation and industry group

---

[1] The indexes are calculated differently from those for the occupation and industry groups. For a detailed description of the index calculation, see the *Monthly Labor Review* Technical Note, "Estimation procedures for the Employment Cost Index," May 1982.

25. Specified compensation and wage adjustments from contract settlements, and effective wage adjustments, private industry collective bargaining situations covering 1,000 workers or more (in percent)

Measure	Annual average		Quarterly average							
	1984	1985	1984			1985				1986
			II	III	IV	I	II	III	IV	I^p
Specified adjustments:										
Total compensation [1] adjustments, [2] settlements covering 5,000 workers or more:										
First year of contract	3.6	2.6	3.5	2.7	3.7	3.6	3.5	2.0	2.0	0.3
Annual rate over life of contract	2.8	2.7	3.2	3.1	2.0	2.7	3.4	3.0	1.4	1.2
Wage adjustments, settlements covering 1,000 workers or more:										
First year of contract	2.4	2.3	2.6	2.1	2.3	3.3	2.5	2.0	2.1	.8
Annual rate over life of contract	2.4	2.7	2.7	2.6	1.5	3.2	2.8	3.1	1.9	1.6
Effective adjustments:										
Total effective wage adjustment [3]	3.7	3.3	.9	1.2	.7	.7	.8	1.2	.5	.6
From settlements reached in period	.8	.7	.1	.2	.3	.1	.2	.2	.1	.0
Deferred from settlements reached in earlier periods	2.0	1.8	.7	.7	.2	.6	.5	.5	.2	.4
From cost-of-living-adjustments clauses	.9	.7	.2	.3	.2	.1	.1	.4	.1	.2

[1] Compensation includes wages, salaries, and employers' cost of employee benefits when contract is negotiated.

[2] Adjustments are the net result of increases, decreases and no changes in compensation or wages.

[3] Because of rounding total may not equal sum of parts.

p = preliminary.

26. Average specified compensation and wage adjustments, major collective bargaining settlements in private industry situations covering 1,000 workers or more during 4-quarter periods (in percent)

Measure	Average for four quarters ending–							
	1984			1985				1986
	II	III	IV	I	II	III	IV	I^p
Specified total compensation adjustments, settlements covering 5,000 workers or more, all industries:								
First year of contract	4.7	4.2	3.6	3.4	3.4	3.1	2.6	2.3
Annual rate over life of contract	3.5	3.2	2.8	2.6	2.7	2.7	2.7	2.6
Specified wage adjustments, settlements covering 1,000 workers or more:

Contracts without COLA clauses	1.6	1.4	1.0	1.4	1.7	(1)	(1)	(1)

[1] Data do not meet publication standards.

p = preliminary.

27. Average effective wage adjustments, private industry collective bargaining situations covering 1,000 workers or more during 4-quarter periods (in percent)

Effective wage adjustment	Average for four quarters ending–						
	1984		1985				1986
	III	IV	I	II	III	IV	p
For all workers:[1]							
Total	4.2	3.7	3.6	3.5	3.5	3.3	3.1
From settlements reached in period	1.0	.8	.7	.9	.9	.7	–
Deferred from settlements reached in earlier period	2.1	2.0	2.2	1.9	1.8	1.8	1.7
From cost-of-living-adjustments clauses	1.2	.9	.7	.7	.8	.7	.8
For workers receiving changes:							
Total	5.0	4.4	4.5	4.2	4.3	4.1	4.0
From settlements reached in period	3.7	3.0	2.9	2.9	2.8	3.4	2.9
Deferred from settlements reached in earlier period	4.2	4.0	4.2	3.9	3.7	3.7	3.5
From cost-of-living-adjustments clauses	3.2	2.7	2.3	2.3	2.8	2.2	2.5

[1] Because of rounding total may not equal sum of parts.

– Data not available.

p = preliminary.

28. Specified compensation and wage adjustments from contract settlements, and effective wage adjustments, State and local government collective bargaining situations covering 1,000 workers or more (in percent)

Measure	Annual average		Second 6 months 1985p
	1984	1985	
Specified adjustments:			
Total compensation [1] adjustments, [2] settlements covering 5,000 workers or more:			
First year of contract	5.2	4.2	3.8
Annual rate over life of contract	5.4	5.1	5.3
Wage adjustments, settlements covering 1,000 workers or more:			
First year of contract	4.8	4.6	4.4
Annual rate over life of contract	5.1	5.4	5.6
Effective adjustments:			
Total effective wage adjustment [3]	5.0	5.7	4.1
From settlements reached in period	1.9	4.1	3.2
Deferred from settlements reached in earlier periods	3.1	1.6	.9
From cost-of-living-adjustment clauses	(4)	(4)	(4)

[1] Compensation includes wages, salaries, and employers' cost of employee benefits when contract is negotiated.

[2] Adjustments are the net result of increases, decreases, and no changes in compensation or wages.

[3] Because of rounding total may not equal sum of parts.

[4] Less than 0.05 percent.

p = preliminary.

29. Work stoppages involving 1,000 workers or more

Measure	Annual totals		1985									1986		
	1984	1985	Apr.	May	June	July	Aug.	Sept.	Oct.	Nov.	Dec.	Jan.p	Feb.p	Mar.p
Number of stoppages:														
Beginning in period	62	54	3	2	2	9	6	11	6	3	2	4	3	3
In effect during period	66	61	8	8	8	13	18	20	20	13	9	7	7	9
Workers involved:														
Beginning in period (in thousands)	376.0	323.9	6.2	6.9	15.7	50.1	15.3	69.5	76.6	26.2	8.2	7.6	24.0	12.3
In effect during period (in thousands)	391.0	584.1	14.8	15.1	28.5	56.9	66.8	93.9	119.3	47.0	38.0	12.0	28.4	38.7
Days idle:														
Number (in thousands)	8,499.0	–	220.5	203.3	454.3	500.2	669.7	931.4	1,433.0	651.2	666.4	170.0	308.5	411.3
Percent of estimated working time[1]	.04	.03	.01	.01	.02	.02	.04	.04	.06	.04	.03	.01	.02	.02

[1] Agricultural and government employees are included in the total employed and total working time: private household, forestry, and fishery employees are excluded. An explanation of the measurement of idleness as a percentage of the total time worked is found in "'Total economy' measure of strike idleness," *Monthly Labor Review*, October 1968, pp. 54-56.

[1] Area is generally the Standard Metropolitan Statistical Area (SMSA), exclusive of farms. L.A.-Long Beach, Anaheim, Calif. is a combination of two SMSA's, and N.Y., N.Y.-Northeastern N.J. and Chicago, Ill.-Northwestern Ind. are the more extensive Standard Consolidated Areas. Area definitions are those established by the Office of Management and Budget in 1973, except for Denver-Boulder, Colo. which does not include Douglas County. Definitions do not include revisions made since 1973.

[2] Foods, fuels, and several other items priced every month in all areas; most other goods and services priced as indicated:.

M - Every month.

1 - January, March, May, July, September, and November.

2 - February, April, June, August, October, and December.

[3] Regions are defined as the four Census regions.

The population size classes are aggregations of areas which have urban population as defined:

A-1 - More than 4,000,000.

A-2 - 1,250,000 to 4,000,000.

B - 385,000 to 1,250,000

C - 75,000 to 385,000.

D - Less than 75,000.

Population size class A is the aggregation of population size classes A-1 and A-2.

- Data not available.

NOTE: Local area CPI indexes are byproducts of the national CPI program. Because each local index is a small subset of the national index, it has a smaller sample size and is, therefore, subject to substantially more sampling and other measurement error than the national index. As a result, local area indexes show greater volatility than the national index, although their long-term trends are quite similar. Therefore, the Bureau of Labor Statistics strongly urges users to consider adopting the national average CPI for use in escalator clauses.

Sweden	3.1	2.8	3.1	3.0	3.0	2.9	2.8	2.7	2.8

---

[1] Quarterly rates are for the first month of the quarter.

[2] Major changes in the Italian labor force survey, introduced in 1977, resulted in a large increase in persons enumerated as unemployed. However, many persons reported than they had not actively sought work in the past 30 days, and they have been provisionally excluded for comparability with U.S. concepts. Inclusion of such persons would more than double the Italian unemployment rate shown.

- Data not available.

NOTE: Quarterly and monthly figures for France, Germany, and Great Britain are calculated by applying annual adjustment factors to current published data and therefore should be viewed as less precise indicators of unemployment under U.S. concepts than the annual figures.

46. Annual data: Employment status of the civilian working-age population, ten countries

Lost workdays	36.2	36.1	35.8	35.9	35.8	37.0	41.1

---

[1] Total cases include fatalities.

[2] The incidence rates represent the number of injuries and illnesses or lost workdays per 100 full-time workers and were calculated as:
(N/EH) X 200,000, where:

N = number of injuries and illnesses or lost workdays.
EH = total hours worked by all employees during calendar year.
200,000 = base for 100 full-time equivalent workers (working 40 hours per week, 50 weeks per year.)

[3] Excludes farms with fewer than 11 employees since 1976.

SALES PUBLICATIONS

BLS Bulletins

Employment Projections for 1995: Data and Methods. Bulletin 2253, 131 pp., $6.50 (GPO Stock No. 029-001-02897-1). Provides the latest industry and occupational employment projections for the year 1995.

Injuries to Construction Laborers. Bulletin 2252, 26 pp., $1.75 (GPO Stock No. 029-001-02893-8). Summarizes the results of a survey of construction laborers who were injured on the job in October 1983.

Injuries to Warehouse Workers. Bulletin 2257, 24 pp., $1.75 (GPO Stock No. 029-001-02898-9). Summarizes the results of a survey of warehouse workers who were injured on the job in September 1984.

Occupational Projections and Training Data, 1986 Edition. Bulletin 2251, 202 pp., $10 (GPO Stock No. 029-001-02896-2). Provides detailed statistics on current and projected occupational employment and related information on occupational demand and supply.

Productivity Measures for Selected Industries, 1958–84. Bulletin 2256, 295 pp., $14 (GPO Stock No. 029-001-02894-6). Updates through 1984 indexes of output per employee for the industries currently included in the U.S. Government's productivity program.

Relative Importance of Components in the Consumer Price Indexes, 1985. Bulletin 2261, 36 pp., $2.25 (GPO Stock No. 029-001-02895-4). Presents data on the expenditure or value weights of components in the Consumer Price Indexes (CPI-U and CPI-W), expressed as a percentage of all items.

Area Wage Surveys

These bulletins cover office, professional, technical, maintenance, custodial, and material movement jobs in major metropolitan areas. The annual series of 70 is available by subscription for $102 per year. Individual area bulletins are also available separately.

Davenport-Rock Island-Moline, Iowa-Illinois, Metropolitan Area, February 1986. Bulletin 3035-7, 43 pp., $2.25 (GPO Stock No. 829-001-00079-9).

Huntsville, Alabama, Metropolitan Area, February 1986. Bulletin 3035-5, 42 pp., $1.75 (GPO Stock No. 829-001-00077-2).

Newark, New Jersey, Metropolitan Area, January 1986. Bulletin 3035-6, 55 pp., $2.75 (GPO Stock No. 829-001-00078-1).

Washington, DC—Maryland—Virginia, Metropolitan Area, March 1986. Bulletin 3035-8, 39 pp., $2.25 (GPO Stock No. 829-001-00080-2).

Industry Wage Surveys

These studies include results from the latest BLS survey of wages and supplemental benefits, with detailed occupational data for the Nation, regions, and selected areas (where available). Data are useful for wage and salary administration, union contract negotiation, arbitration, and Government policy considerations.

Petroleum Refining, June 1985. Bulletin 2255, 35 pp., $2.25 (GPO Stock No. 029-001-02892-0).

Periodicals

CPI Detailed Report. Each issue provides a comprehensive report on price movements for the month, plus statistical tables, charts, and technical notes. $4 ($25 per year).

Current Wage Developments. Each issue includes selected wage and benefit changes, work stoppages, and statistics on compensation changes. $2 ($21 per year). March issue features Employment Cost Index, December 1985; Major Work Stoppages: 1985; Union Membership of Employed Wage and Salary Workers. April issue features major collective bargaining settlements in private industry, 1985.

Employment and Earnings. Each issue covers employment and unemployment developments in the month plus regular statistical tables on national, State, and area employment, hours, and earnings. $4.50 ($31 per year). April issue features note on reintroduction of labor force data by area of residence.

Producer Price Indexes. Each issue includes a comprehensive report on price movements for the month, plus regular tables and technical notes. $4.25 ($29 per year).

Area Wage Summaries

Columbus, GA-AL, March 1986. 3 pp.
El Paso-Alamogordo-Las Cruces, TX-NM, March 1986. 3 pp.
Logansport-Peru, IN, April 1986. 6 pp.
Middlesex, Monmouth, and Ocean Counties, NJ, December 1985. 7 pp.
Nashville-Davidson, TN, February 1986. 3 pp.
Savannah, GA, March 1986. 3 pp.

BLS Summaries

Occupational Earnings in Banking, Selected Metropolitan Areas, 1985. Summary 86-2 (No. 2 of 2). 6 pp.

Occupational Earnings and Wage Trends in Metropolitan Areas, 1985. Summary 86-1 (No. 3 of 3). 10 pp.

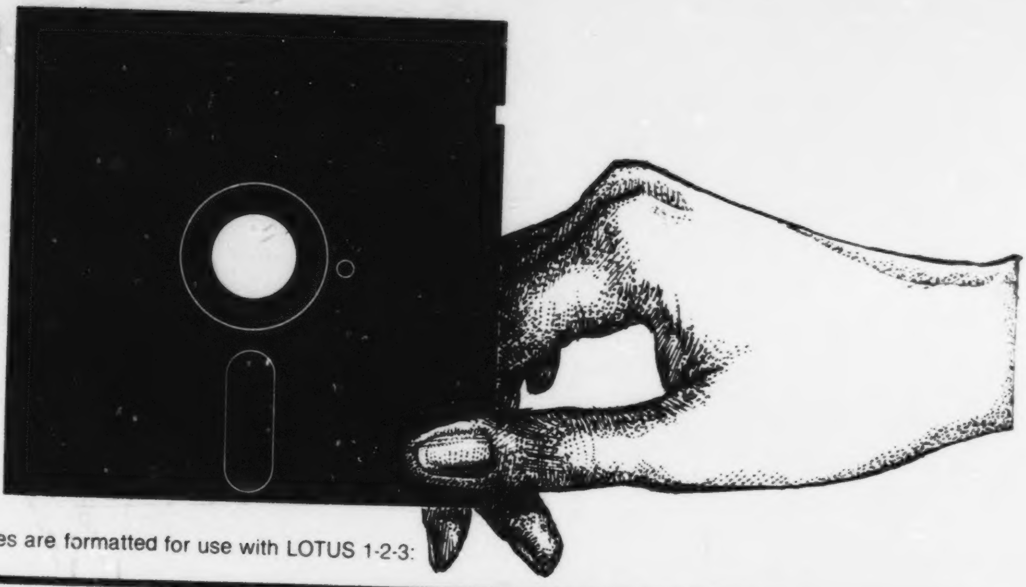
BLS Data Diskettes now available



BLS data users now can tore and manipulate he Bureau's data series n their personal, BM-compatible microcomputers

The following data diskettes are formatted for use with LOTUS 1-2-3:

Monthly

Employment, hours, and earnings from the establishment survey—national monthly and annual average data for 256 industrial series for the current year-to-date and the 3 prior years. Single diskette, $35. Annual subscription of 12 monthly diskettes, $288.

Labor force, employment, and unemployment from the Current Population Survey—monthly and annual average information on the employment and unemployment experience of the Nation's population classified by age, sex, and race for 282 series for the current year-to-date and he 3 prior years. Single diskette, $35. Annual subscription of 12 monthly diskettes, $288.

Producer Price Indexes—selected commodity groupings by stage of processing for the most recent 13 months. Single diskette, $35. Annual subscription of 12 monthly diskettes, $288.

Quarterly

Employment Cost Index–quarterly measures of change in total compensation (wages, salaries, and employer costs for employee benefits) and in wages and salaries only; 180 series beginning in 1980–81 and 120 series from 1975 to the most recent quarter. Single diskette, $35. Annual subscription of 4 quarterly diskettes, $104.

National productivity indexes—63 quarterly labor productivity and cost measures for business, nonfarm business, nonfinancial corporations, and manufacturing from 1947 to the current quarter. Also, 24 annual multifactor productivity measures (output per unit of combined labor and capital inputs) for private business, private nonfarm business, and manufacturing from 1948 to the current year. Single diskette, $35. Annual subscription of 8 quarterly diskettes, $196.

U.S. export and import price indexes—quarterly export and import price indexes for 450 Standard Industrial Trade Classification categories for the most recent 8 quarters. Single diskette $35. Annual subscription of 4 quarterly diskettes, $104.

Annual

Economic projections to 1995—average annual output, total employment, hours, and wage and salary employment for 1984 and projected 1985–95 for 150 industries. Single diskette, $35.

Foreign labor statistics–129 annual indexes of manufacturing productivity and labor costs for the United States and 9 foreign countries from 1950 to 1984; and levels of the labor force, unemployment, and related measures for the United States and 9 countries from 1954 to 1985. Single diskette, $35. Annual subscription of 4 quarterly diskettes, $104.

Industry productivity data—annual indexes showing change over time in the relationship between the output of an industry and the employee hours expended on the output for over 130 industries: most start in 1958 and go to the most recent year. Also, annual Federal Government productivity indexes showing the change over time in the relationship between the output of the combined organizations within a function and the employee years expended on that output from 1967 to 1984. Single diskette, $35.

Occupational injury and illness data—annual number of work related injuries and illnesses or lost workdays per 100 full-time employees from 1981 to 1984. Single diskette, $35.

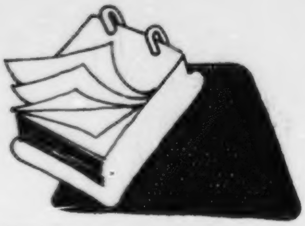
Labor Month In Review



LABOR LAW STUDY. The Department of Labor began a study of the Nation's labor laws and collective bargaining practices to identify possible conflicts between these laws and practices and the kind of labor-management cooperation the Department is seeking to encourage. Stephen I. Schlossberg, Deputy Under Secretary for Labor-Management Cooperation, and Steven M. Fetter, his executive assistant, discuss the project in a background paper issued June 16. Here are brief excerpts:

DOL's position. The Department of Labor has taken a strong position in support of labor-management cooperation as an important prerequisite to America's return to preeminence in the world marketplace. Secretary of Labor William E. Brock has said that our country must develop a "solid atmosphere of cooperation, based on the concept of worker dignity and equality and grounded in a mutual respect for collective bargaining, [which] enables both unions and management to maintain individual integrity while working for the good of all."

Experiments spread. A 1982 survey found that at least one-third of the Fortune 500 companies, with both organized and unorganized work forces, have some form of participative management or quality of work life program in operation and that these efforts have, by and large, resulted in measurably improved employee morale and increased productivity.

While many of the more experimental efforts may have resulted from endangered corporations needing wage concessions to give them a better chance at economic survival, the programs' achievements have proved to be so attractive that they have captured the attention of other firms not in financial trouble. While noteworthy worker participation plans are in place at AT&T with the Communications Workers of America and the International Brotherhood of Electrical Workers, at Xerox with the Amalgamated Clothing and Textile Workers Union, and in several steel companies with the United Steelworkers of America, two of the most auspicious are between the UAW and the GM-Toyota joint venture at New United Motors Manufacturing, Inc. (NUMMI) in Fremont, California, and between Ford Motor Company and the UAW.

Within many companies, a new cooperative attitude is reordering labor-management priorities so that unions are more concerned about the financial health of the business and management seeks a relationship which enhances the role of workers by seeking their input and ideas. Both sides see the value of replacing distrust and hostility with equity and sharing. While the parties recognize that there are risks in altering their traditional antagonistic relationship, they are convinced that the risks are even greater if they do nothing at all. Thus, because of factors beyond their control, but also with an interest in achieving the differing yet complementary goals of increased productivity and an improved quality of work life, certain segments of the labor-management community are becoming "partners in the enterprise."

Legal considerations. Unfortunately, the mutual desires of labor and management to cooperate have not put an end to their problems. The new hybrids they have created—often called quality of work life, employee involvement, worker participation, labor-management participation teams or committees, or any of a number of other motivational names—do not easily fit within the framework of our existing labor laws and labor-management culture.

The history of labor relations in this country has been, and to a large degree continues to be, characterized by confrontation. In most cases, the relationship, from initial organization through contract negotiation and administration, has been driven by law and legal considerations; the motivation for action has rarely been cooperation, mutuality of interest, or principles of human relations. Rules, not goals, have set the tone.

In the past, our labor relations have exhibited a remarkable ability to adapt to the changing needs of an evolving, but flourishing, industrial economy. Now we must wait to see whether the creative steps taken by labor and management to deal with a declining industrial manufacturing base can pass muster with the agencies and courts charged with interpreting our labor laws. If they cannot, then the two sides must work together to formulate the legislative strategy necessary to modify our laws to permit such innovation.

Working together. The American economy can ill afford to continue the escalation of confrontation that has traditionally divided labor and management. There will always be bargaining to distribute gains and losses between the parties; but in those aspects of the relationship that clearly involve shared interests, we should emphasize mutuality rather than militancy and seek to advance a new ordering of labor relations which aligns manager and worker on the same side—working together for the common good. Clearly, cooperation and problem solving offer more promise for productive labor-management relationships than the combat of the past. If our statutes and practices are an impediment to change, we must be willing to consider reasonable alterations in that basic framework to encourage a process that will ultimately benefit society as a whole.

Copies of the 32-page paper are available from Office of Labor-Management Relations and Cooperative Programs, Room N5402, U.S. Department of Labor, Washington, DC 20210. ☐

An analysis of regional employment growth, 1973–85

Shifts in regional economic performance and job growth generally have been from the Snowbelt to the Sunbelt; however, many factors can alter regional advantage, often suddenly

PHILIP L. RONES

Reference to the transfer of economic power from old industrial regions of the North to the South and West has become almost a cliche. The term "Sunbelt" is generally associated with population growth, economic prosperity, and a bright future, while "Snowbelt" connotes economic decline. How then do we reconcile these perceptions with the fact that New England, which a decade ago was rapidly losing population and jobs, presently has the lowest unemployment rate of any region; or that in late 1985, a considerable majority of the States in the West and South had jobless rates above the national average; or that, since the recession trough in late 1982, housing costs in Boston have risen dramatically while those in Houston, an often cited symbol of the prosperity of the new South, have declined?[1]

Such recent developments have made it clear that the situation is more complex than commonly thought. There has been, and most likely will continue to be, a shift in economic influence towards the South and West. Such movements are the expected result of historic differences in regional income, wages, and cost of living, as well as shifts in the importance of each region's geographic and resource endowments. Yet within that context, long-term changes in the structure of our economy, cyclical swings, and unanticipated "shocks" all can alter regional advantage. The economic "Power Shift,"[2] as it has been called, is clearly not as immutable as once thought.

The first section of this article describes some of the changes in regional employment over the past decade or so, with particular emphasis on the industrial components of those changes. The second section examines some of the reasons for dramatically uneven regional employment growth, focusing on such aspects as population and business migration, regional income inequality, and economic shocks. Finally, because New England has done the most in recent years to break the stereotype of the Snowbelt versus Sunbelt economies, some of the causes of the resurgence of that region's economy are examined.

Shift-share analysis

The technique employed in examining trends in regional job growth is called shift-share analysis, a statistical method which has been commonly used in regional analysis for several decades.[3] It can be used to allocate regional growth among three components: national share, industry mix, and regional share. National share indicates the employment change that would have occurred if a region's employment growth rate had equaled the national growth rate over the study period. Industry mix shows the amount of regional employment growth attributable to the region's initial industry mix; that is, it reflects a region's mix of fast- and slow-growth industries. Finally, regional share indicates whether a region's industries performed better or worse than the national average for each industry.[4] This last component is essentially a measure of competitive advantage—the end result of the many varied factors which can cause uneven regional growth. For analytical purposes, the industry mix and regional share statistics are the more interesting, because they relate regional changes to developments at the national level.

Philip L. Rones is a senior economist in the Office of Employment and Unemployment Statistics, Bureau of Labor Statistics.

The data. This analysis uses data from the Current Employment Statistics Survey, a nationwide survey of business establishments which provides information by industry on employment, hours, and earnings of workers on nonagricultural payrolls. The survey is a cooperative effort of the State Employment Security Offices and the BLS, through which data are obtained from employer reports filed monthly with the State agencies.

For this analysis, State data were aggregated into the nine census divisions, shown in exhibit 1. (The terms region and division, in reference to geography, often are used interchangeably in this analysis.) Industry data were treated at the major division level, with manufacturing divided into its durable and nondurable goods components.[5] The exclusion of agriculture from survey coverage would have only a minor impact on most regions, but for the West North Central area, the exclusion could be critical. Certainly, poor agricultural performance would be felt throughout that region's nonagricultural sector. Even so, estimates presented here probably understate the economic difficulties in that part of the country.

    - Washington
    - Oregon
    - Alaska

Region-by-industry employment matrices were prepared for 1973, 1975, 1979, and 1985. All years but 1975 were chosen because they represented relative high points in the business cycle. Data for 1975 were included to isolate the effects of the 1973–75 recession on regional performance.

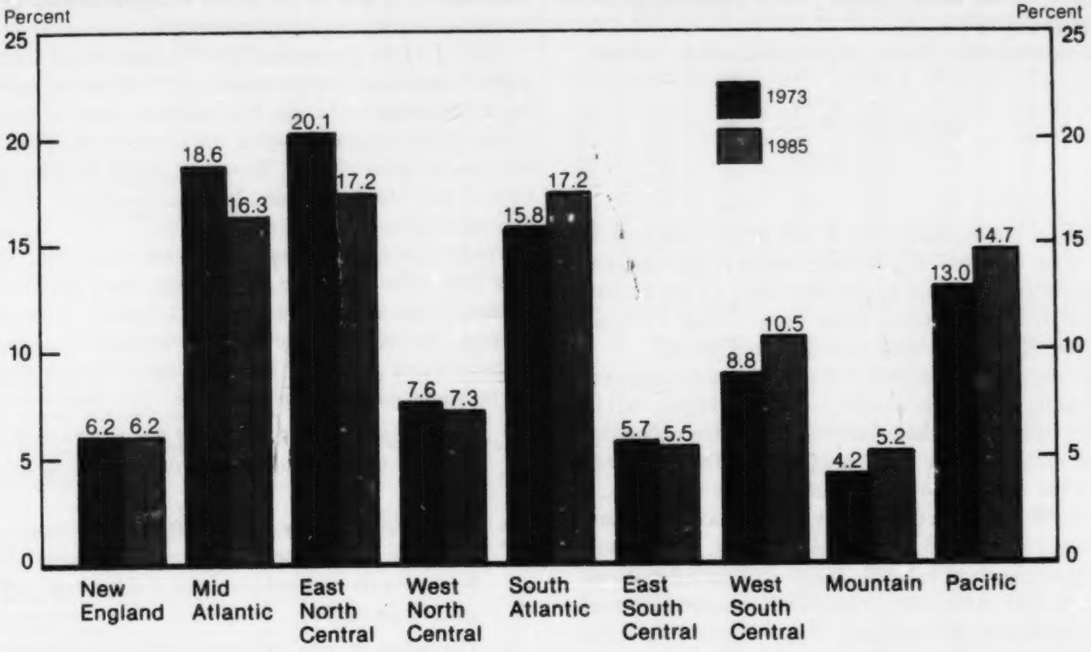
There is often quite valid concern about the usefulness of the regional aggregations, because regions are not homogeneous economic units. For instance, population and employment growth in the South Atlantic region have been well above the national average principally because a single State, Florida, has dominated the region in terms of both size and relative rate of growth. California similarly dominates the Pacific region. However, the argument of a lack of homogeneity is probably no more valid in its application to regional data than it would be to State or local data. The local economies that make up many States are as diverse in their industrial makeup and performance as are the State economies that make up any region. Hence, there is enough to gain in using any of these "aggregated" data—local, State, or regional—to warrant their use in labor market analysis.

The results. The first two columns in table 1 show the actual change in each region's total employment between 1973 and 1985 and the national share component of the change. The national share represents the employment growth that a region would have experienced if its number of jobs had expanded at the national average rate over the 12-year period. Where the actual change in employment is greater than the national share, a region's employment grew at a faster rate than the national average. The West South Central region, for example, grew twice as fast as the Nation as a whole. Conversely, where actual growth is less than national share, a region's jobs grew at a slower than average rate. Employment in the East North Central region, for example, grew only one-third as fast as the national average.

It is not surprising that the slowest employment growth areas were generally in the Northeast and Midwest and the fastest in the South and West. The regional variation, however, was quite dramatic. At the extremes, the East North Central region's nonfarm payroll jobs grew by only 8 percent over the study period, while employment gains of 57 percent were registered in the Mountain States. The range of employment growth performance is reflected in the changing regional distribution of national employment, shown in chart 1.

As previously stated, the industry mix column of the table reflects the advantage or disadvantage bestowed on a region by virtue of its industrial makeup in the initial year of the study. A region would stand to grow more slowly than the average if it had a relatively large share of industries with slower than average growth over the 12-year period—government, construction, and, more importantly, manufacturing, particularly nondurable goods. A region would be favored if it began the period with a higher than average

Chart 1. Distribution of nonagricultural payroll employment by census division, 1973 and 1985



employment concentration in mining and in any of the service-producing industries other than government. Because this statistic compares a region's industry mix to a national average, the net impact of the industry mix (and regional share, for that matter) across regions is by definition zero.

It should be kept in mind that the industry mix statistic has substantial limitations. Because manufacturing showed relatively slow growth over the study period, a region with little or no manufacturing would appear to have a positive industry mix. Manufacturing activity, however, is generally viewed as a prerequisite for strong growth in the service sector. Thus, the effect of this hypothetical industry distribution would undoubtedly show up as poor regional share performance in other industries.

As expected, the area most hurt by its poor industry mix was the East North Central region, with its initially high proportion of heavy manufacturing jobs. That region's employment would have increased by an additional 420,000 over the study period if the area had had an "average" industry mix in 1973. But in virtually all cases, the industry mix statistic is a poor second to regional share in explaining the gap between actual regional job growth and the national average. The Middle Atlantic States, for instance, experienced little industry mix impact and yet had very slow growth, while the South Atlantic region, also with a neutral industry distribution, experienced quite rapid growth. The West South Central, Mountain, and Pacific regions all prospered, in terms of the industry mix measure, from their emphasis on mining (except in recent years) or service-sector jobs and their relative lack of factory employment. However, in none of these rapid-growth regions did the 1973 industry mix explain as much as 20 percent of employment change above or below the national share.

The regional share measure explains most of the geographic differences in employment growth. The Middle Atlantic and East North Central regions combined registered 5 million fewer jobs than their industry mix alone would have predicted, while the Southern and Western gainers (minus the East South Central) added 5 million jobs more than their "fair share." The following analysis, then, will focus on the regional share component of change, identifying the industries in which regional growth has been particularly strong or weak and examining the change in regional advantage and disadvantage that occurred within three subperiods of the 1973–85 span.

The regional share component reflects how a region's industries performed compared to the national average for each industry. The interpretation of the results is simplified by the use of the indexes shown in table 2 in place of absolute numbers.[6] If an industry within a particular region grew at the same rate as that industry nationwide, then the index figure would be 1. An index greater than 1 represents better than average performance (a figure of 1.100, for example, represents employment growth 10 percent above average), and an index of less than 1 represents below-average performance.

The regional share index, RSI, is calculated as follows:

$$\mathrm{RSI} = \frac{E_{ir}^{t+1}}{E_{ius}^{t+1}\left(E_{ir}^{t}/E_{ius}^{t}\right)}$$

where E_{ir} is employment in each industry (i) and each region (r) (or division); E_{ius} is employment in each industry for the United States as a whole; and t and $t+1$ are the base year and final year in any comparison—either 1973 and 1985, respectively, or some narrower time frame.

More simply, the calculation divides actual industry employment in each region in 1985 (or another target year) by what the figure would have been had the region maintained its base-year share of industry employment. The calculation ignores the rate of growth of each industry nationally, a factor that shows up in the industry mix statistic. For example, New England had 5.47 percent of U.S. construction industry employment in 1973. Had it maintained that proportion in 1985, it would have had .0547 × 4,646,000 (total 1985 construction employment), or approximately 254,000 construction jobs. Actual employment slightly exceeded that mark—258,000. Thus, the regional share index is 258,000/254,000, or 1.016.

In this presentation, the mix and share components of regional change are separated as if they were unrelated factors, but in reality, they are quite interrelated. In a study of the effects of industry mix on State unemployment rates, Robert McGee estimated that the indirect (or "spillover") effect of industry mix was, on average, about 15 percent higher than the direct effect.[7] For example, an area with an unfavorable industry mix is likely to experience above-average unemployment (or below-average employment growth) not only in its disadvantaged industries but also in its stronger ones. The measure used here identifies only the direct effects of industry mix; the spillover effects are incorporated in the regional share component. Thus, the true impact of a poor industry mix is understated in the results for that component, and the dichotomy used here to some extent oversimplifies a complex relationship.

Table 1. Components of change in nonagricultural payroll employment by census division, 1973–85

[Numbers in thousands]

Census division	Employment change, 1973–85	Components of change		
		National share	Industry mix	Regional share
New England	1,317	1,267	12	62
Middle Atlantic	1,512	3,840	51	−2,379
East North Central	1,252	4,148	−419	−2,477
West North Central	1,306	1,562	68	−324
South Atlantic	4,600	3,249	−60	1,411
East South Central	970	1,173	−146	−57
West South Central	3,475	1,809	127	1,539
Mountain	1,852	869	150	833
Pacific	4,317	2,677	234	1,406

NOTE: See text footnote 4 for description of components of change.

Table 2 shows the regional share indexes for all nonfarm payroll employees for the entire 1973–85 period and for three subperiods. The top line indicates that, at the extremes, the West South Central and Mountain divisions had competitive gains of about 20 percent, while the East North Central and Middle Atlantic had losses of more than 15 percent relative to the national average.

The RSI patterns for many regions have changed markedly over time. (For simplicity of language, RSI's significantly greater or less than 1 will be termed "gains" or "losses," although, technically, they describe movements *relative to a national average* rather than absolute changes.) Among the highlights of the RSI trend results:

- New England, formerly one of the worst performers in terms of employment growth, is now among the best.
- The Middle Atlantic States suffered their worst performance in the late 1970's; even in recent years, Pennsylvania continued to exert a downward pull on the 3-State totals.
- The failure of the East North Central to recoup manufacturing job losses has been felt in all sectors in recent years. The cumulative effects are the worst suffered by any region.
- The entire West North Central region has fared poorly in the 1980's, largely because of weakness in the agricultural sector. The exclusion of agriculture from the employment data probably serves to understate the weakness in the region's economy.
- The South Atlantic and East South Central areas both mirrored national performance through the late 1970's. Since then, the former, paced by Florida's boom, has outperformed all other regions, while its more industrialized neighbor has fared quite poorly.
- The West South Central, Mountain, and Pacific regions each experienced gains throughout the three subperiods.

The health of a region's manufacturing industries is generally regarded as the most important and most visible indicator of the area's economic performance. It is in the construction industry, however, that a region's fortunes are most dramatically reflected in the index. In all of the regions in each of the three subperiods examined, only three times (out of 27 chances) was the construction RSI closer to 1 than the region's total RSI; that is, construction almost always showed more dramatic shifts in regional advantage than did the all-employee totals. This is because construction is the industry most dependent on population growth. Many urban

Table 2. Regional share index for nonagricultural payroll employment by major industry and census geographic divisions, selected periods, 1973–85

NOTE: A regional share index greater than 1 represents faster than average industry growth; a value less than 1 represents slower than average growth. See text for further explanation.

areas in the Northeast and Midwest regions have shown very slow growth or absolute declines in population in recent decades, a factor which results in excess housing stock, depressed housing prices, and vastly reduced demand for new residential construction. Likewise, substantial expansion of commercial footage would be unlikely in a stagnant local economy. Conversely, those Southern and Western regions experiencing a rapid influx of both population and business have had to provide new housing, plants, and office space for newcomers.

The RSI's reflect the relationship between construction activity and both population and job growth. For example, while construction activity nationwide was down substantially during the years 1973–75, New England's employment performance for the industry was about 13 percent worse than average, but the West South Central States experienced a relative increase of nearly 20 percent. The construction RSI's reflect the West South Central division's standing as the best performer during that recessionary period in terms of employment growth; it was second only to the Mountain region in population growth.[8]

Outside of developments in mining, the 1979–85 performance of construction in both Midwest divisions was the worst of any region-industry combination. The loss of nearly 20 percent in the regions' employment share is in marked contrast to the 30-percent gain for New England. The former is a dramatic indication of the Midwest's industrial and agricultural woes, while the latter reflects not only New England's improved overall economy but also a catching-up after years of lagging construction activity.

For the entire 1973–85 span, manufacturing is the only industry division for which a decline in regional share reflects an absolute drop in jobs. This is because nationwide manufacturing employment declined by about 800,000 during that period. Thus, the RSI's for durable and nondurable manufacturing closely reflect the regional redistribution of factory jobs. Virtually all of the durable goods job losses occurred in the Middle Atlantic and East North Central divisions. (The East South Central and West North Central's near-unity RSI's reflect a small absolute loss due to the sector's national employment decline.) Their regional share losses, in terms of jobs, were more than 400,000 and 800,000, respectively, or about 19 and 22 percent. Five regions were strong gainers, paced in relative terms by the Mountain States, followed by the Pacific, New England West South Central, and South Atlantic.

The Middle Atlantic States were the only region to experience serious job losses in both durable and nondurable manufacturing. New England continued to suffer from the long-term decline in its textiles and apparel industries in the earlier years of the study period, but experienced little further erosion of nondurables employment after 1979. The only substantial winners in nondurables were the West South Central, Mountain, and Pacific regions.

The industries in the service-producing sector tend to follow the overall regional pattern of population and economic growth. The use of aggregated industry data limits the analysis of these industries. For example, while real estate employment probably follows the economic trends of each region, finance and insurance, which are "exportable," may follow a different pattern. The aggregated data, of course, cannot be used to address this point.

Government employment trends are interesting in that they often differ substantially from regional averages. For example, between 1979 and 1985, New England gained more than its fair share of employment in virtually every industry, but had one of the lowest rates of government employment growth. In the Pacific States, government employment also lagged total regional job growth, largely reflecting California's imposition of restrictions on State and local taxing power.

In summary, the Nation's regions have experienced virtually every pattern of job growth over the 12-year study period—consistently good, as in the Pacific, Mountain, and West South Central; consistently bad, as in the East North Central; improving, as in New England; and deteriorating, as in the East South Central. Strength in manufacturing probably has the broadest impact on regional economic well-being (with certain exceptions, such as the West North Central States where farming is so critical). However, that well-being is most dramatically reflected in construction activity, which can increase or decrease precipitously in response to changing regional fortunes. Service-sector employment most closely mirrors a region's overall population and employment patterns.

Why these shifting fortunes?

Up to this point, the evidence presented has documented the change in regional employment performance, particuarly as it relates to regions' relative competitive position in each industry. What causes these changes in regional advantage? The complexity of this question is reflected in the fact that analysts have not been successful in explaining a substantial portion of regional growth differences. Several important regional growth factors are discussed here—migration, regional income and wages, business location decisions, and economic shocks. The list obviously is not exhaustive, but only representative of the wide range of possible regional growth forces. Finally, some key elements of the economic renaissance in New England are examined.

Migration and jobs. The relationship between population and job growth is complex. It is perhaps best viewed as a cycle that, once begun, is self-sustaining and reinforcing. Certainly, the availability of jobs in an area is an attraction to jobseekers from other regions. Michael Greenwood and Gary Hunt have estimated that in metropolitan areas each 100 additional jobs attract about 45 employed net migrants, with local residents filling the remaining openings.[9] However, migration in and of itself results in a substantial increase in employment above and beyond the migrant's own job. These jobs can be filled by either additional migration or increased labor force participation of the indigenous population. This direction of causation—with population growth causing job expansion—would be reflected in the regional share indexes for industries providing locally consumed products.

Migrants may influence labor demand in several ways.[10] For example, they may bring with them assets or income sources above their wages. Retirees are the prime example of the indirect effect of migration on jobs because the retirees themselves have little or no direct effect on local labor markets. Migrants may cause an increase in demand for infrastructure (roads, schools, utilities, and housing). They may also transport qualities that change the human capital makeup of the sending and receiving areas, to the extent that their age, skills, education, or entrepreneurial talent may be different than the average in either area. Migration may directly affect local labor force participation rates, in that the demographic characteristics of the migrants may differ from the averages in the receiving area. In fact, migrants tend to be concentrated in the 20-to-34 age range, have the highest levels of education, and are somewhat disproportionately male.[11] Also, migrants may influence the prices and profitability of goods and services by changing demand for those items; housing would be the most common example of this.

Table 3 shows percentage changes in population and nonagricultural payroll employment by geographic division between 1973 and 1985.[12] The columns in which the regions are ranked from 1 to 9 according to those changes show that

New England and the East South Central division break an otherwise close match between population and employment change rankings. The jump in New England's employment, despite slow population growth, resulted in a 5-point increase in the region's employment-population ratio, a gain which was more than triple the national average.[13] The East South Central's employment ratio declined a percentage point, for the worst regional performance. The strong relationship between employment and population growth, with causation running in both directions, is obvious.

Regional income and wages. The second explanation for the shift in regional economic power towards the South and West falls under the general heading of regional income (or factor price) inequality. One common theory states that if the factors of production—labor, capital, and so forth—are free to move between regions in order to obtain their highest return, convergence of factor prices among regions will occur in the long run.[14] As an example, table 4 shows regional per capita income in relation to the national average. While per capita income changes may come from several sources, wage rates are by far the most important factor.[15]

All other things being equal, firms will tend to locate where labor costs are low. Workers, on the other hand, are attracted by high wages, but even so, there has been substantial migration from high- to low-wage areas, as from the Midwest to the South. One partial explanation for this trend is the historic regional difference in living costs, which gave wages earned in the South more real purchasing power than those earned in higher-cost regions. The key to migration is in the relationship between wages and job growth. Mancur Olson, citing his own work and that of Charles Hulten and Robert Schwab, provides a theoretical framework for such migration from high- to low-wage regions.[16] Olson proposes that regional economic growth in the United States (and worldwide) is largely dependent on the level of cartelization in each region. In this argument, cartelization refers to "any organizations or groups that lobby for favorable legislation and administrative rulings or act cartelistically to influence prices or wages."[17] Although labor unions are most often cited in this regard, the theory applies equally to producers, professional associations, and so forth.

Olson suggests that the older the region, the more established are these special interests and the more difficult it becomes for many firms to compete in the restrictive environment. One result of these forces is "supra-competitive" wages in the Midwest. Firms which do not benefit from location-specific advantages (proximity to markets or natural resources) or that are less efficient cannot compete in the high-wage environment and will fail or locate elsewhere. Hulten and Schwab conclude that this effect increases productivity and has reduced jobs in the North as employers in that region limit employment until the marginal product of labor equals the "inflated" wage.

Table 3. Percent change in total population and nonagricultural payroll employment by census division, 1973–85

Census division	Percent change, 1973–85		Regional ranking[1]	
	Population	Employment	Population	Employment
New England	4	28	7	5
Middle Atlantic	−1	11	9	8
East North Central	2	8	8	9
West North Central	5	22	6	6
South Atlantic	22	38	4	4
East South Central	12	22	5	7
West South Central	29	51	2	2
Mountain	37	57	1	1
Pacific	26	43	3	3

As the economic situation in the high-wage Midwest has deteriorated, particularly since 1979, the lack of adequate downward flexibility of wages in response to labor market changes has led to an outflow of jobs.[18] Thus, high wages are insufficient to attract migrants in the absence of job growth. In contrast, there has been considerable migration to the high-growth, and relatively high-wage, Pacific region.[19] Olson suggests, however, that low wages will cease to draw industry and workers to the South as the regional wage differentials disappear and as the South loses its economic and social peculiarities. The same institutional arrangements that have led to market inefficiencies in the North, he predicts, will accelerate in the South.

That a general convergence of regional incomes has occurred over time is clearly shown in table 4. During the past decade, however, regional changes have not necessarily led towards further convergence. Thus, it seems that while wage differentials have been an important factor in the location decisions of individuals and businesses, they may no longer contribute as heavily to those decisions in the future.

Regional location—the firm. As we have seen, many of the factors affecting an individual's decision to migrate may be similar to those that influence a firm's investment location decision. Other factors that may be as important to the firm as to the individual include climate, population density, and taxes. While the intricacies of location theory are beyond the scope of this analysis, it would be a serious omission to completely ignore the topic.

Two important conclusions can be drawn from a survey of the literature on business location: These decisions tend to be quite complex and to be firm- and industry-specific—why else would new business investment be so geographically dispersed, even within specific industries? Also, such predictable factors as wages, taxes, unionization, and energy costs fail to explain much of the differences in investment location.

Researchers are unanimous in their finding that the differences in regional employment growth rates generally are not the result of actual movement of firms out of the North and into the South and West.[20] The notion of firm relocation is based largely on the observed migration of textiles manufacturers out of New England and into North and South Carolina in the 1940's and 1950's. In fact, regional employment growth is mostly the result of the formation of new firms and the expansion of existing ones.

How are business investment decisions made? One technique used in location factor studies is to list factors assumed to be, or identified by businesses as being, important in the location decision and to rank States according to those factors.[21] These may include taxes, wages, unionization, energy costs, and cost of living, among others. As expected, high-growth States tend to perform well in such rankings. Studies may also include such factors as supply and quality of labor and proximity to markets. Generalizations about regional advantages in the second group of measures are more difficult to make. However, the importance of such factors makes it clear that "business climate," in the low-wage, low-tax sense, is not enough to attract some investment. For example, a new firm may require certain highly technical consulting services available in only a few areas of the country. That requirement alone may make other considerations irrelevant.

Lynn Brown and fellow analysts have shown that the location factors do not overwhelmingly favor a particular region.[22] Substantial investment occurs in States with a high-wage or high-energy-cost profile, for example. In fact, the authors find that the most common factors associated with regional investment account for only a third of the regional variation. The conclusion is that States should not feel helpless in the face of uncontrollable negative business climate factors. Development strategies can be devised to attract those firms which may benefit from the State's positive attributes. As will be shown later in the discussion, New England has benefited from its historical position as a manufacturing and finance center, as well as from its history of academic excellence. Substantial economic progress has been made there in the face of other business climate factors which are not so favorable.

Economic "shocks." The factor that may best explain recent regional shifts in economic performance is economic "shocks," those largely unforeseen circumstances that not only change the Nation's competitive position in the world economy but also change the regional locus of economic power within the United States. Bernard Weinstein and others have described the takeoff in economic growth in the Southern and Western States in terms of W.W. Rostow's stages-of-growth model, in which sustained growth does not occur without some dramatic external stimulus.[23] Prior to World War II, the South was a relatively underdeveloped economy—the only employment shares above the national average were in the most basic sectors, agriculture and basic energy.[24] World War II saw the infusion of billions of dollars in investment into the Sunbelt, with an estimated 60 percent of the $74 billion wartime expenditures going to 15 Southern and Western States.[25] Particularly important was the birth and continued expansion of substantial high-technology and aerospace industries in the Sunbelt. This event is seen as the takeoff necessary for sustained growth according to the Rostow model. The distribution of defense funds continues to have a strong regional impact. However, as New England, another large defense contracting region, witnessed during the years following the Vietnam conflict, such dependence makes a region's economy susceptible to the vagaries of defense budgets.[26]

While not of the same magnitude as the effects of World War II on regional development, changing energy prices are generally cited as the most important shock event in the recent experience. First, rising energy prices, which prevailed throughout most of the study period, change the relative regional cost of production and transportation. To some extent, labor costs also may be affected, as workers attempt to recoup losses in their standard of living. Second, price changes affect the revenues of producers and, in effect, redistribute income from energy "have-not" to energy "have" regions. While the energy sector itself is not a large employer, the employment effects in related industries—finance, drilling equipment, and technical services, among others—can be quite large.

Regarding the first issue, table 5 suggests the effects on residential business consumers of the two large OPEC price increases during the 1970's. Hans Landsberg stresses that

Table 4. Index of per capita income by region, selected years, 1940–85
[National average=100]

Year	Region									Standard deviation
	New England	Middle Atlantic	East North Central	West North Central	South Atlantic	East South Central	West South Central	Mountain	Pacific	
1940	126	132	112	81	77	49	64	87	132	30.9
1950	107	117	111	95	81	61	81	95	120	19.5
1960	110	116	108	92	84	69	82	93	119	17.5
1970	109	113	104	94	91	75	85	91	111	13.0
1977	102	106	105	97	93	81	92	94	111	9.1
1985	114	110	99	98	96	77	92	92	110	10.9

SOURCE: Bureau of Economic Analysis, U.S. Department of Commerce. Data through 1977 are published in Lynn Brown, "Narrowing Regional Income Differentials," *New England Economic Review* (Federal Reserve Bank of Boston), September/October 1980, p. 37.

one must consider both actual cost levels, in that certain regions characteristically have greater energy costs, and changes in those levels.[27] The latter would be most likely to affect regional competitive positions. For example, while industrial energy users in the South paid 26 percent less than the national average in 1970, that advantage had declined to 12 percent by 1980. Landsberg indicates that "it may be much more punishing for the prosperity of an area with low energy prices to suffer drastic boosts, while still remaining *below* the national average, than for a high-cost area to undergo modest boosts and still stay *above* the national average."[28]

Residents of the Northeast may have suffered the most from energy price rises because they were triply penalized; they use more energy, they depend disproportionately on expensive fuel oil, and fuel oil prices rose faster than those for natural gas, its chief competitor. But with recent decontrol of natural gas prices, the current softness in the world oil market, and the additional cost some low-energy-price areas have faced since 1980 due to nuclear plant construction, regional advantage in the energy area has tended to narrow.[29]

While the above discussion focuses on the energy consumer, recent shifts in world oil prices have considerably altered the fortunes of energy-producing areas as well. For example, Weinstein and others have commented, not too facetiously, that "the OPEC oil embargo did more to revive Appalachia than ten years and $10 billion of federal aid."[30] Partly as a result of strong growth in its mining sector, West Virginia's jobless rate was about the national average in the late 1970's.[31] However, as weak energy prices, conservation, and concerns over pollution have lessened the demand for coal, more recent jobless rates for the State have been twice the national average. Likewise, Texas had very low jobless rates, with some labor shortages, during the late 1970's and early 1980's, and the State was relatively unaffected by the 1981–82 recession. More recently, however, lower energy prices have contributed to a deterioration in the State's job market. Jobless rates in early 1986 were above the national average, housing prices were weak, and housing foreclosure rates were the highest in the country.[32] Similar examples of energy-price induced boom and bust economies can be seen in Alaska, Wyoming, and several other States in the Mountain and West South Central regions.

While defense expenditures and energy prices may be among the most visible of shock factors which are exogenous to regional economies, many other such events occur continuously. For example, foreign exchange rates, foreign policy objectives, social expenditures, and technological discoveries all affect regions differently. Thus, while certain redistribution of regional wealth and economic growth is structural in nature, unanticipated events can render many regional "power shifts" transitory.

New England's restructured economy

The key ingredient in the economic turnaround in New England probably has been time. While the deterioration of the economy in the industrial Midwest is fairly recent, New England had begun a period of "deindustrialization" at least four decades ago. The region's economy initially was dominated by textiles; in 1950, for example, textiles firms employed 265,000 of the region's workers.[33] By 1984, that figure had been reduced to 50,000, both because of the early outmigration of firms to the Carolinas and the long-term structural decline in the industry nationwide. However, even as the region's economic performance deteriorated, New England already had in place many of the requirements for reindustrialization. That this process has occurred is dramatically demonstrated by the regional share indexes in table 2; over the 1973–85 period, New England's performance in nondurable goods was the worst in the Nation, while that in durables was nearly the best. Time and certain other prerequisites have allowed a major industrial restructuring of the region's economy.

What were the prerequisites for the reindustrialization of New England? John Hekman and John Strong suggest that development of a high technology industrial region is most likely when three factors are at work—a strong research, or scientific, component; industrial experience; and financial resources.[34] In tracking New England's development, the authors cite the region's strong historical standing in all three areas.

The Massachusetts Institute of Technology was founded in the 19th century partly as a way of advancing industrial technology. By the early 1900's, the relationship between MIT and the area's industry was beginning to make original scientific contributions in the areas of electrical and chemical engineering. Many companies in the region were formed or expanded based on the skills and discoveries of MIT-trained scientists.

Because scientific manpower tends to be in short supply, high tech firms cluster around academic centers. Many

Table 5. Average residential and industrial energy prices by region, 1970 and 1980

[Dollars per billion BTU's]

Region	1970	1980	Percentage increase, 1970–80
Residential:			
United States	$1,403	$4,472	219
Northeast	1,598	5,808	263
Midwest	1,430	4,388	207
South	1,411	4,136	193
West	1,098	3,603	228
Industrial:			
United States	628	3,166	403
Northeast	847	4,256	402
Midwest	723	3,130	333
South	462	2,795	505
West	651	3,167	386

firms are then spawned from these early enterprises, and these start-ups virtually never involve relocation.[35] One reason is that new firms need access to the same limited pool of technical manpower. Thus, the regional manpower advantage of a major academic center is in product design and development, not necessarily in the production phase.

For over a century, New England has been on the cutting edge of new technology—in the manufacture of textiles, guns, and machine tools, for example, and later, in applications of electricity. Some older firms have continued their technological innovations into today's high tech fields; others can trace their lineage back to those firms.[36] Thus, to some extent it is inaccurate to describe today's high-tech firms as having "chosen" to locate in New England. To a large degree, they were already there.

One reason for the continuation of the region's tradition of industrial innovation is that it has remained a center for venture capital. Not only are the region's banks and other major financial institutions more inclined toward venture finance than those in other areas, but the region has also been a leader in the formation of venture capital firms. And, in another example of the university-business link, some academic institutions, such as Harvard and MIT, have been actively involved in risk financing.[37] Conversely, the lack of venture capital has been cited as an impediment to the growth of high tech firms in other regions, such as the Southeast.[38]

New England was hit very hard by the 1973–75 recession, in large part because of the combined effects of the oil price increases and earlier defense cutbacks. However, this overall weakness tended to obscure the fact that certain of the region's industries were expanding. Many of the budding high tech firms were little affected by the downturn. As these firms matured, they entered the production stages, in which labor costs begin to take on a greater role in profitability. While New England's per capita income levels have never fallen below the national average, its wage rates have been low and were driven lower by the 1969–70 and 1973–75 recessions.[39] (The reader should also note that the per capita income figures are inflated by the region's traditionally high labor force participation rates.) The evidence indicates that capital/labor ratios in New England have been very low over the study period, and firms have taken advantage of these relatively low labor costs.[40] Recently, New England and other regions have seen the movement of some production facilities to very low-wage foreign countries such as those in the Pacific Basin. This is to be expected in the highly cost-sensitive and labor-intensive mass production phase of the firms' growth cycle. What employment effect these movements will have in the future is unclear.

Another key factor most frequently cited in New England's resurgence is the overall quality of education in the area, from the public schools through the top levels of higher education. The region has higher than average rates of high school and college graduation and a disproportionately large cadre of scientific manpower.[41] Bernard Wei stein and Harold Gross cite educational attainment of th population as one of the key impediments to continue growth in some Sunbelt areas and the critical factor in Ne England's prominence.[42]

Thus, New England has benefited from the close an long-standing relationship among the business, academic and financial communities. Employment growth has accelerated due to the combined influence of low real wages an a highly skilled and educated work force. At the same time slow population growth has allowed much of the region's economic expansion to show up in a rapid rise in its employment-population ratio and in declining joblessness.

While the region suffered from rising energy costs and defense cutbacks in the early 1970's, energy prices have remained soft in recent years, and the region's defense contracts have grown in the 1980's. It should be pointed out that New England's economy remains susceptible to changes in those two factors.[43] The region provides clear evidence that an area can key its growth to the manufacturing sector if its industries are innovative and government is responsive.[44]

Conclusions

Over roughly the last decade, the Nation has seen a continuation of the long-term trend of employment and population shifts from much of the Northeast and Midwest to the South and West. However, the rather poor recent performance of the East South Central region and the economic rebirth of New England demonstrate that the shift in economic power from Snowbelt to Sunbelt is far from immutable.

Many of the factors that have made the South and West so attractive to both firms and individuals are becoming less pronounced. Interregional differences in wages and cost of living have narrowed, as have differences in nonpecuniary factors of urban life—population density, pollution, crime, and congestion. Just as much of the North is affected by a declining tax base and aging infrastructure, some areas of the South have been unable to keep pace with the growing demands for new infrastructure. For example, water availability may be the "shock" factor that some day forces a halt to the Southwest's rapid growth.[45]

Other developments may place limits on growth in some rapidly expanding areas. The economies of the West South Central and Mountain regions benefited greatly from the energy boom of the 1970's and early 1980's, but have been hurt badly by the recent collapse in the price of oil. And, as mentioned earlier, the quality of education in much of the South is often perceived as a limiting factor. Also, the South's attractiveness as a low-wage area for production may be declining as the drawing power of foreign competitors increases.

None of this is to say that an economic shift back towards the North is inevitable, or even expected. Rather, the evidence suggests that regional advantage is often short-lived. The lesson of New England is that it takes time to restructure a region's economy to meet the requirements of changing national and world economic environment. But the period of decline may actually create the conditions for future growth, while the forces of growth may ultimately result in a loss of competitive edge.

A decade ago, an analysis of the future of the Northern regions' economies typically read like a eulogy. Today, the scenario of continued deterioration of the Northern areas and rapid growth in the South and West seems not nearly so inevitable. □

[3] For examples of the application of shift-share analysis, see M.F. Petrulis, "Regional Manufacturing Employment Growth Patterns," *Rural Development Research Report No. 13* (U.S. Department of Agriculture, Economics, Statistics, and Cooperative Service, June 1979); and Edgar S. Dunn, Jr., "A Statistical and Analytical Technique for Regional Analysis," *Papers and Proceedings of the Regional Science Association*, Volume 6, 1960, pp. 97–112.

[4] The three components of regional change are defined as follows:

$$E^{t+1} - E^{t} =$$

$$E^{t}\left(\left(E^{t+1}_{us}/E^{t}_{us}\right) - 1\right) \qquad \text{(National share)}$$

$$+\ \Sigma_i E^{t}_i\left(\left(E^{t+1}_{ius}/E^{t}_{ius}\right) - \left(E^{t+1}_{us}/E^{t}_{us}\right)\right) \qquad \text{(Industry mix)}$$

$$+\ \Sigma_i E^{t}_i\left(\left(E^{t+1}_i/E^{t}_i\right) - \left(E^{t+1}_{ius}/E^{t}_{ius}\right)\right) \qquad \text{(Regional share)}$$

where:

E = total regional employment;
E_i = regional employment in industry i;
E_{us} = total national employment;
E_{ius} = national employment in industry i; and
t and $t+1$ = the base and target years, respectively.

[5] The use of this technique does have several limitations. First, as applied here, the use of broad aggregate industries ignores the possible effects of industry distributions within those aggregates. For example, if a region had a higher than average proportion of durable goods industries in the base year, that would have a negative effect on the region's industry mix statistic. However, it is possible that the particular region had a very large share of employment in fast-growth durable goods industries. In that event, the industry mix statistic would paint too negative a picture of the manufacturing sector's effect on the region's industry mix. It would be unusual, however, for a region's employment mix within a broad industry group to differ so markedly from the national average as to change the sign of the industry mix statistic for that particular industry (unless, of course, if the statistic were already close to zero).

Second, because the technique must be applied over a discrete time period, the choice of the base year distribution for the industry mix statistic may bias the results. Changes in a region's industry mix over time may alter the ratio of slow- to fast-growth industries. The longer the period to which the technique is applied, the greater the effect of a change in a region's industry mix relative to a national average. A check of the data used here shows that this potential problem has little effect. The industry mix statistics for the most recent period, 1979 to 1985, show essentially the same pattern as those for the entire 1973–85 span, although the levels are much smaller because they have a much smaller regional employment growth to explain. Thus, regional industry distributions have not changed in a pattern markedly dissimilar to that of the entire Nation.

[6] Unlike individual industries, the regional totals are affected by industry mix in that they reflect the growth rates in each industry, weighted for the change in the relative size of the industry. The top line totals thus incorporate the (usually small) effects of industry mix—that is, they measure the combined effects of regional share and industry mix.

A note on communications

The *Monthly Labor Review* welcomes communications that supplement, challenge, or expand on research published in its pages. To be considered for publication, communications should be factual and analytical, not polemical in tone. Communications should be addressed to the Editor-in-Chief, *Monthly Labor Review*, Bureau of Labor Statistics, U.S. Department of Labor, Washington, D.C. 20212.

The revised Consumer Price Index: changes in definitions and availability

The Consumer Price Index for January 1987 will incorporate some new series and will reflect changes in several old series; the availability of some indexes will be affected

JOHN L. MARCOOT AND RICHARD C. BAHR

The release of the January 1987 Consumer Price Index (CPI) in February will introduce updated market baskets that reflect population distributions from the 1980 census of population and spending patterns from the 1982-84 Consumer Expenditure Survey. This release will be part of a 5-year program to update the CPI market basket and incorporate numerous technical enhancements.[1]

Although the CPI is a measure of price change for a market basket of constant quality and quantity, it also needs to retain its relevance to consumers' experience by pricing items currently purchased. New consumer purchasing patterns occur as a result of changes in a number of factors, such as relative prices, income, tastes, demographic characteristics, technological changes, and population shifts. Thus, periodic revisions of the CPI are necessary to incorporate updated versions of the market basket.

This article is one of a series that provides detailed information about the CPI revision. It highlights the changes that will occur in the availability and in the definitions of indexes. Many of the changes derive from shifts that have occurred in the spending patterns of the American public. Nearly five decades of spending patterns as reflected in the CPI expenditure weighting patterns and the corresponding relative importance of major groups are shown in table 1. A later article will discuss the new expenditure weights in detail.

Item indexes

One clear trend in consumer spending has been a reduction in the relative importance of expenditures for food, especially grocery food. Although it is not immediately obvious from the data in table 1, there have been corresponding increases in importance for new products and services such as video recorders and day care. To ensure the most accurate CPI possible, it has been necessary to allocate more pricing and calculation resources to these new and growing expenditure categories, with the correlative result that proportionately fewer resources will be available for items of declining importance. This means new indexes for previously unpriced products will become available. But it also means that there will be some reduction in product detail for expenditure categories with declining relative importance. The discontinuation of an index does not mean that the item is no longer priced for the CPI. All of the previously priced items will continue to be priced, but with much smaller samples. The relative proportions that these items constitute of the new combined strata (class of similar items) to which they are assigned will also be subject to annual updating through the sample rotation process.[2]

Exhibit 1 summarizes the definitions for new item indexes and explains the definitional changes that some other indexes are undergoing. These definitional changes arise from the need to combine some previously separate items, the addition of some previously unpriced items, and conceptual or coverage changes which enhance the measurement or interpretation of the index.

Some of the items that are being discontinued as separate

John L. Marcoot is the manager of the CPI Revision Program and Richard C. Bahr is an economist in the Office of Prices and Living Conditions, Bureau of Labor Statistics.

item strata because of their reduced relative importance have significant applications independent of their use in the CPI. To accommodate users of these indexes, BLS will continue to publish a limited number of them as special sub-strata CPI-U indexes. These sub-strata indexes will be based on extremely small samples and will be less reliable than the pre-1987 numbers. Footnote 3 lists the item strata that are being discontinued and indicates whether a corresponding sub-strata index will be available.[3]

Beginning with the CPI-U for January 1983, BLS adopted an improved method—called rental equivalence—for estimating homeowner shelter costs.[4] (The change was made in January 1985 for the CPI-W.) The 1987 CPI revision continues the definitional and coverage features associated with that change. In addition, it incorporates two new refinements consistent with that change. First, the new index for materials, supplies, and equipment for home repairs, which combines three more detailed old indexes, will include for pricing only those types of items that would be purchased by tenants and exclude those typically purchased by landlords for major repairs or capital improvements. Second, the rental value of owner-used vacation property is included in lodging while out of town.

The definitional treatment of premium costs for health care insurance will have a change which will affect the structure of the expediture weights for health insurance, but not the methodology for estimating price changes affecting the costs of health insurance. Beginning with January 1987, the CPI will define the cost of health insurance as the portion of premium payments which is retained by the insurer in the form of profits and operating expenses. The portion of the premium which is either paid directly by the insurer to health care providers or as reimbursements to policyholders will no longer be defined as a health insurance expenditure, but rather as a direct medical care expenditure.

This definitional change will slightly modify the method used for estimating changes in health insurance premiums. An indirect method has been used to estimate the changes in costs of health insurance. The expenditure for health insurance has been defined as total consumer premium payments. The price change for these premiums has been e mated with a combination of the changes in cost for cove medical services and the changes in premium retained insurers for operating costs and profit.[5]

The revised definition will result in the portion of health insurance expenditure that is paid as benefits by insurer being included in the directly priced medical ca strata, for example, physician services, hospital room, a eye care. The result of this treatment is that the expenditu weights of these directly priced medical care strata will increased, and they will also receive a greater proportion the price quotations in the CPI. The expenditure weight f health insurance will represent only the portion of the pr mium retained by the insurers, and changes in its costs wi continue to be estimated using an indirect pricing procedur that relies both on CPI changes for covered medical expense and secondary data on premiums retained by insurers. Thi definitional change will result in the discontinuation of th index for "Other medical care services."

Local area indexes

As announced in 1984, BLS has allocated the price quotation samples among the 91 pricing areas in a sample desigr which will produce the most accurate national CPI possible with the funds authorized. The decision to improve the national CPI estimate will reduce the frequency of publication for some areas. Beginning in 1987, semiannual average indexes will replace bimonthly indexes for 12 currently published areas. (See table 2.) These semiannual average indexes, which are the averages of the 6-month periods from January through June and from July through December, will be published with the release of the July CPI in August and the January CPI in February.

The method of calculating the averages for a semiannual average index derives from the one currently used for calculating annual average indexes which BLS publishes at the end of each year. Because monthly and bimonthly indexes are not published in those areas, the first step will be intermediate monthly and bimonthly calculations for use in the average computation. For those items which are priced monthly,

Table 1. The Consumer Price Index market basket by major expenditure group and benchmark year

[Percent distribution]

Major group	Wage earners and clerical workers (CPI-W)						All urban consumers (CPI-U)		
	1939[1]	1952[2]	1963[3]	1977[4]	1984[5]	1982–84[6]	1977[4]	1982[5]	1982–84[6]
Food and beverages	35.4	32.2	25.2	20.5	21.3	20.1	18.8	20.1	18.0
Housing	33.7	33.5	34.9	40.7	34.9	39.2	43.9	37.7	42.2

Other goods and services	4.9	4.8	5.7	4.4	5.2	5.0	4.4	5.0	5.1

[1] Relative importance for the expenditure survey period 1934–36 updated for price change.

[2] Relative importance for the expenditure survey period 1950 updated for price change.

[3] Relative importance for the expenditure survey period 1960–61 updated for price change.

[4] Relative importance for the expenditure survey period 1972–73 updated for price change.

[5] Relative importance for the expenditure survey period 1972–73 with the rental equivalence approach to homeowners' costs updated for price change. The rental equivalence approach to homeowners' costs was introduced into CPI-U effective January 1983 and into the CPI-W effective January 1985.

[6] Relative importance for the expenditure survey period 1982–84. Revised indexes which require expenditure weights updated for price change between the survey period and December 1986 will differ from those shown.

Exhibit 1. Title and definition changes in the Consumer Price Index, beginning with January 1987 data

New series title	Definition change
Food and beverages	
Fresh other breads, biscuits, rolls, and muffins[1]	Combines "Other breads" and "Fresh biscuits, rolls, and muffins."
Cookies, fresh cakes, and cupcakes[1]	Combines "Fresh cakes and cupcakes" and "Cookies."
Other bakery products[1]	Combines "Fresh sweetrolls, coffeecake, and donuts" and "Frozen and refrigerated bakery products and fresh pies, tarts, and turnovers."
Ham[1]	Combines "Ham other than canned" and "Canned ham."
Other pork, including sausage[1]	Combines "Sausage" and "Other pork."
Other dairy products, including butter[1]	Combines "Butter" and "Other dairy products."
Oranges, including tangerines (Old title—Oranges)	Adds tangerines.
Other fresh fruits (Old title—Same)	Excludes tangerines.
Fruit juices and frozen fruit[1]	Combines "Frozen fruit and fruit juices" and "Fruit juices other than frozen."
Other processed vegetables[1]	Combines "Cut corn and canned beans except lima" and "Other canned and dried vegetables."
Sweets, including candy[1]	Combines "Candy and chewing gum" and "Other sweets."
Carbonated drinks[1]	Combines "Cola drinks, excluding diet cola" and "Carbonated drinks, including diet cola."
Coffee[2]	Combines "Roasted coffee" and "Freeze dried and instant coffee."
Seasonings, condiments, sauces, and spices[1]	Combines "Seasonings, olives, pickles, relish" and "Other condiments."
Miscellaneous prepared foods, including baby food[1]	Combines "Miscellaneous prepared foods" and "Other canned and packaged prepared foods."
Distilled spirits (at home)[1]	Combines "Whiskey (at home)" and "Other alcoholic beverages (at home)."
Housing	
Lodging while out of town (Old title—Same)	Adds the rental equivalence value of owner-used vacation property.
Materials, supplies, and equipment for home repairs	Combines "Paint and wallpaper, supplies, tools, and equipment," "Lumber, awnings, glass, and masonry," and "Plumbing, electrical, heating, and cooling supplies." Excludes capital improvements and major repair items typically provided by landlords.
Other maintenance and repair commodities (Old title—Miscellaneous supplies and equipment)	Adds hardsurface floor covering and landscaping items not previously priced.
Other household fuel commodities (Old title—Same)	Adds wood, charcoal, and peat not previously priced.
Other video equipment	Consists of video cameras, recorders, players, cassettes, disks, and related equipment.
Major household appliances	Consists of index series titles: "Refrigerator and home freezer;" "Laundry equipment;" and "Stoves, ovens, dishwashers, and air conditioners."
Stoves, ovens, dishwashers, and air conditioners	Combines parts of "Stoves, dishwashers, vacuums, and sewing machines" and "Office machines, small electric appliances, and air conditioners."
Information processing equipment	Consists of home computers, telephones, and other electronic and office equipment for nonbusiness use.
Other housefurnishings	Consists of index series titles: (1) "Floor and window coverings, infants', laundry, cleaning, and outdoor equipment;" (2) "Clocks, lamps, and decor items;" (3) "Tableware, serving pieces, and nonelectric kitchenware;" (4) "Lawn equipment, power tools, and other hardware;" and (5) "Sewing, floor cleaning, and small kitchen and portable heating appliances."
Sewing, floor cleaning, and small kitchen and portable heating appliances	Combines parts of "Stoves, dishwashers, vacuums, and sewing machines" and "Office machines, small electric appliances and air conditioners."
Lawn equipment, power tools, and other hardware (Old title—Same)	Adds hand tools.
Laundry and cleaning products including soap[1]	Combines "Soaps and detergents" and "Other laundry and cleaning products."
Household paper products and stationery supplies[1]	Combines "Cleansing and toilet tissue, paper towels, and napkins" and "Stationery, stationery supplies, and giftwrap."
Other household, lawn, and garden supplies[1]	Combines "Miscellaneous household products" and "Lawn and garden supplies."

Exhibit 1. Continued—Title and definition changes in the Consumer Price Index, beginning with January 1987 data

New series title	Definition change
Gardening and other household services	Combines "Moving, storage, freight, household laundry and dry cleaning services" with "Gardening and lawn care services," which was previously unpublished.
Indoor plants and fresh flowers	
Care of invalids, elderly and convalescents in the home	Not published initially; will be published when sample is adequate.
Apparel	
Men's suits, sport coats, coats, and jackets[1]	Combines "Men's suits, sportcoats, and jackets" and "Men's coats and jackets."
Women's underwear, nightwear, hosiery, and accessories (Old title—Women's underwear, nightwear, and hosiery)	Adds women's accessories.
Sewing materials, notions, and luggage	Combines "Sewing materials and notions" with part of "Jewelry and luggage."
Watches	Formerly was part of "Jewelry and luggage."
Jewelry	Formerly was part of "Jewelry and luggage." Excludes watches.
Transportation	
New cars (Old title—Same)	Transaction expenditure not reduced by market value of vehicle traded in.
New trucks[3]	Transaction expenditure not reduced by market value of vehicle traded in.
New motorcycles	Transaction expenditure not reduced by market value of vehicle traded in.
Used cars (Old title—Same)	Purchase of used cars from the business sector. Excludes value of used cars sold or traded by consumers.
Automobile registration, licensing; and inspection fees[1]	Combines "State registration," "Automobile inspection," "Local registration" (unpublished), and "Drivers' license."
Other automobile related fees (Old title—Same)	Adds rentals of vehicle equipment.
Other intercity public transportation[1]	Combines "Intercity bus fares" and "Intercity train fares"
Intracity public transportation[1]	Combines "Intracity mass transit" and "Taxi fare."
Medical care	
Prescription drugs (Old title—Same)	Adds benefits paid by consumer-purchased insurance.
Nonprescription drugs and medical supplies (Old title—Same)	Excludes eyeglasses.
Physicians' services (Old title—Same)	Adds benefits paid by consumer-purchased insurance.
Dental services (Old title—Same)	Adds benefits paid by consumer-purchased insurance.
Eye care	Includes all consumer out-of-pocket expenses for eye care commodities and services as well as benefits paid by consumer-purchased insurance.
Services by other medical professionals	Includes services rendered by therapists, nurses, and other practitioners including both out-of-pocket expenses and benefits paid by consumer purchased insurance.
Hospital and related services (Old title—Hospital and other medical services)	Adds previously unpriced outpatient hospital services.
Hospital room (Old title—Same)	Adds benefits paid by consumer-purchased insurance.
Other inpatient services	Consists of other hospital and inpatient services including nursing and convalescent home service, paid out of pocket as well as benefits paid by consumer-purchased insurance.
Outpatient services	Consists of emergency room services, laboratory fees, and x-rays, including both out-of-pocket expenses and benefits paid by consumer purchased insurance.
Health insurance (unpublished) (Old title—Same)	Portion of premium paid by consumer not paid out in benefits.
Entertainment	
Sport vehicles, including bicycles[1]	Combines "Sport vehicles" and "Bicycles."
Other sporting goods[1]	Combines "Indoor and warm weather sport equipment" and "Other sporting goods and equipment" as well as equipment for water sports.
Club memberships	Formerly part of "Fees for participant sports."
Fees for participant sports, excluding club memberships	Portion of "Fees for participant sports" exclusive of club membership dues and fees.
Fees for lessons or instructions	Formerly part of "Other entertainment services."
Other entertainment services (Old title—Same)	Includes film processing, photographer fees, veterinarian services, pet services, and rental of miscellaneous entertainment equipment.

Exhibit 1. Continued—Title and definition changes in the Consumer Price Index, beginning with January 1987 data

New series title	Definition change
Other goods, services	
Tobacco and smoking products (Old title—Tobacco products)	
Other toilet goods and small personal care appliances, including hair and dental products[1]	Combines "Products for the hair, hairpieces, and wigs;" "Dental and shaving products;" and "Other toilet goods and small personal appliances."
Child daycare/nursery school	Not published initially; will be published when sample is adequate.
Technical and other tuition	Not published initially; will be published when sample is adequate.
Legal fees	Consists of the legal fees portion of "Personal expenses."
Banking and accounting expenses	Consist of the safe deposit box rental and bank service charge portion of "Personal expenses" plus fees for accounting services not previously priced.
Funeral expenses	Consist of the funeral services portion of "Personal expenses" plus charges for cemetery lots and vaults not previously priced.

[2] Historical data available back to January 1967.

[3] Historical data available back to January 1984.

such as food at home, an intermediate monthly calculation will be prepared for each of the 6 months. These six calculated numbers will be summed and then divided by six to obtain the semiannual index. A similar but more complex technique is used for items priced bimonthly in each area. An intermediate calculation will be compiled for each of the 3 months that items are actually priced during the 6-month period. The monthly calculation for each of the other 3 months will be interpolated by calculating a geometric mean of the months adjacent to the one being estimated. For example, in an area priced in even-numbered months, a January interpolation would be estimated by taking the geometric mean between the indexes calculations for December and February. Interpolations would be made in a similar manner for March and May. The three intermediate numbers for February, April, and June, calculated with collected prices, would be summed with the three interpolations and divided by six to obtain the semiannual average index for the first 6 months of the calendar year.

The calculation of semiannual indexes for areas in which bimonthly items are priced only in odd-numbered months would use the same methodology except that the data for February, April, and June would be interpolated by using the geometric mean between the calculations for their adjacent months. For example, the June interpolation would be estimated from the calculations made for May and July.

Although BLS will calculate semiannual indexes for these 12 areas from intermediate estimates of monthly data, the samples are much too small to produce a reliable bimonthly or monthly estimate of price change. Estimates based on a small number of observations in a single month would be subject to extremely high volatility resulting primarily from sampling error. The averaging of 6 months of price data increases the reliability of the estimate. The new semiannual index estimates of price change will be as accurate as the old bimonthly index estimates which they replace for the 12 local areas identified in table 2.

The BLS has systematically advised users that local area CPI's (including the new semiannual averages) are subject to substantially more statistical error and variability than the national index. As a result, local indexes should not be used in escalation provisions. Some individuals may have already adopted escalation clauses using one of the local indexes that will change from bimonthly to semiannual publication. After the data for December 1986, it will not be possible to use individual monthly estimates for these 12 areas, and parties to agreements using these indexes may want to agree on some alternative. BLS does not provide contract interpretation assistance but can provide limited technical assistance for transition, if requested by both parties to an agreement.

The use of the new Consolidated Metropolitan Statistical Area (CMSA) definitions, issued by the Office of Management and Budget, resulted in a number of the published areas becoming larger in terms of their sampled geography.[6] Of the 27 local areas to be published, 5 (Anchorage, Buffalo-Niagara Falls, Honolulu, Milwaukee, and San Diego) did not have changes to the geographic coverage currently being priced by BLS. Only Dallas-Fort Worth became smaller, with Wise County being removed from the official definition.

Several areas have had significant expansions of their sampled geography. For example, the New York area now includes Danbury and other parts of Connecticut; the Philadelphia area has added Wilmington and Trenton;

[1] Odd months (Jan., Mar., May, July, Sept., Nov.).

[2] Even months (Feb., Apr., June, Aug., Oct., Dec.).

[3] Includes areas not identified separately.

NOTE: The size class boundaries have changed since 1978. As shown above, the boundaries between the midsized and small areas are variable. Previously, the limits were 1.25 million and above; midsized—385,000 to 1.25 million; small—75,000 to 385,000; and less than 75,000.

Boston now includes some parts of New Hampshire; the Chicago area has three additional counties including Kenosha, WI; Houston has added Galveston; Los Angeles includes Riverside-San Bernardino; and San Francisco includes San Jose. Table 2 contains a complete list of counties for each local area with a published CPI.

Table 2 also shows the population for both the CPI-U and CPI-W in each of the publication areas as a percentage of their respective total U.S. 1980 urban population. If these weights are compared with the weights shown for 1970, one can ascertain the degree of relative population change in each area since 1970. For example, the weight for the CPI-U population in the Northeast region declined from 26.521 in 1970 to 23.997 in 1980. This decline reflects the faster growth rate of the population of the South and West in recent years, compared with the Northeast. Even though the New York area has expanded since 1970, its relative population weight has declined.

The population weight for the San Francisco-Oakland-San Jose area has become larger than that for the Detroit-Ann Arbor area. Based on population growth since 1970 and the expansion of its definition, the San Francisco area has superseded the Detroit area as the fifth largest area covered by the CPI indexes. For that reason, the San Francisco area, beginning with data for January 1987, will be published monthly while the Detroit area will be published bimonthly (even-numbered months). The publication of indexes for Cleveland are changing from even-numbered months to odd-numbered months, D-size (that is, urban areas with populations under 75,000) strata indexes will not be published in the Northeast and West, and indexes will no longer be published for the Scranton-Northeast Pennsylvania area.

Both the CPI-U and the CPI-W for January 1987 will be linked to the present series of each index as of Decemb 1986 to provide a continuous series. For most indexes, th linking will be accomplished by setting the index levels the revised CPI with the updated expenditure weights ar samples equal to those published for the present series December 1986. Each index will move upward or dow ward from the December 1986 level in accordance wit subsequent changes in prices. The local area indexes whic are calculated and published for the odd-numbered month will be linked to their present series in November 1986 an subsequent changes in prices measured from that point i time. For new items and for those items that have undergon significant definition changes, indexes will be introduce with November or December 1986=100.

As in the past, BLS will publish selected indexes using th old expenditure weights for 6 months after the issuance o the revised CPI. Unlike earlier revisions, these overlap indexes will be calculated from the updated item, outlet, an area samples and will differ from the revised indexes onl by their expenditure weights. As a result of a number o enhancements made in the CPI during this and the previou revision, the costly activities of replacing the entire set o item, outlet, and area samples prior to the issuance of the revised CPI have been eliminated. Substantial cost reductions in the revision process were achieved by replacing only those item, outlet, and area samples which were necessary for estimating a CPI based on the 1980 population and the 1982–84 market basket of expenditures. In earlier revisions, the 6-month overlap old series indexes used not only the old expenditure weights but also the old item, outlet, and area samples. The base period for the revised CPI for January 1987 will be 1967=100, the same as for the present index. □

[2] See *BLS Handbook of Methods: Volume 2—The Consumer Price Index*, Bulletin 2134–2 (Bureau of Labor Statistics, 1984), p. 12, for a description of the current rotation process. The post-1986 CPI will have an even broader rotation process as described in Marcoot, "Revision of the Consumer Price Index," pp. 34–35.

[3] The following item strata are being discontinued, but a corresponding sub-strata index will be available:

Other breads
Fresh biscuits, rolls, and muffins
Fresh cakes and cupcakes
Cookies
Crackers and bread and cracker products
Fresh sweetrolls, coffee cake, and donuts
Frozen and refrigerated bakery products and fresh pies, tarts, and turnovers
Ham other than canned
Pork sausage
Other pork
Frankfurters
Bologna, liverwurst, salami
Other lunchmeats
Lamb and organ meats
Butter
Other dairy products
Frozen fruit and fruit juices
Other fruit juices
Cut corn and canned beans except lima
Other processed vegetables
Candy and chewing gum
Other sweets
Margarine
Other fats, oils, salad dressing
Nondairy substitutes and peanut butter
Roasted coffee
Instant and freeze-dried coffee
Seasonings, olives, pickles, relish
Other condiments
Miscellaneous prepared food and baby foods
Other prepared foods
Whiskey at home
Other alcoholic beverages at home
Household linens
Curtains, drapes, slipcovers, sewing materials
Soaps and detergents
Other laundry and cleaning products
Cleansing and toilet tissue, paper towels, and napkins
Stationery, stationery supplies, and gift wrap
Men's suits, sport coats, and jackets
Men's coats and jackets
Boys' coats, jackets, sweaters, and shirts
Boys' suits, trousers, sport coats, and jackets
Girls' coats, jackets, dresses, and suits
Girls' separates and sportswear
State automobile registration
Products for hair, hair pieces, wigs

A sub-strata index will not be available for the following items:

Canned ham
Cola drinks excluding diet cola
Other carbonated drinks
Paint, wallpaper supplies, tools, equipment
Lumber, awnings, glass, masonry materials
Plumbing, electrical, heating, cooling supplies and equipment

Other property maintenance and repair commodities
Stoves, dishwashers, vacuums, and sewing machines
Office machines, small electric appliances, and air conditioners
Miscellaneous household products
Lawn and garden supplies
Moving, storage, freight, household laundry, and dry cleaning
Boys' furnishings
Girls' underwear, nightwear, hosiery and accessories
Sewing materials and notions
Driver's license
Automobile inspection
Intercity bus fares
Intercity train fares
Intracity mass transit
Taxi fare
Anti-infective drugs
Tranquilizers and sedatives
Circulatories and diuretics
Hormones, diabetic drugs, biologicals, and prescription medical supplies
Pain and symptom control drugs
Supplements, cough and cold preparations, and respiratory agents
Eyeglasses
Other professional (medical) services
Other hospital and medical care services
Sports vehicles
Bicycles
Indoor, warm weather sport equipment
Other sporting goods and equipment
Dental and shaving products
Other toilet goods and personal care appliances
Cigarettes
Other tobacco products and smoking accessories

[5] See Marcoot, "Revision of the Consumer Price Index," pp. 36–37.

[6] Because of time constraint, the CPI area samples were drawn on preliminary new Consolidated Metropolitan Statistical Area (CMSA) definitions obtained from the Office of Management and Budget (OMB). When the official definitions were issued, several had been modified slightly. The most notable difference is that Racine, WI, was sampled as a separate area in the Class C (population of 75,000 to 385,000) stratum, whereas the final OMB definition for the Milwaukee CMSA included Racine. Similarly, Monroe County, MI, was dropped by OMB from the Toledo definition and added to Detroit.

Theories of worker satisfaction

Job satisfaction or, in its broader form, work satisfaction, is a difficult entity to define even in simplistic terms. For the individual worker, it exists when the perceived benefits of the work exceed the perceived costs by a margin deemed by the worker to be adequate under the circumstances. It is not, however, a static state and is subject to influence and modification from forces within and outside of the immediate work environment. One school of thought . . . examines the problem in terms of its extrinsic or intrinsic orientation, that is whether the worker is primarily concerned with work as a means to provide fulfillment outside of the job, or finds fulfillment in the work itself, the former perhaps tending to be more of a working-class value and the latter more of a middle-class one. Furthermore, job satisfaction is not the unitary or integrated state that the name would imply. There are multiple facets to the working state, some of which are more satisfying, or perhaps more acceptable, and others less. Job satisfaction at best describes in comparative terms some integrated mean of that state at some point in time. There is no absolute on some infinite scale. At best, we can state that at this particular time one is more satisfied with some aspect of one's job than at some other time.

Human Stress, Work and Job Satisfaction: A Critical Approach (Washington, International Labor Office, 1983), p. 24.

Reconciling divergent trends in real income

Growth rates in real per capita income and real family income diverged between 1970 and 1984 because the concepts and components of the two series reflected economic, social, and demographic changes in different ways

Paul Ryscavage

The real incomes of American families have not grown very much since the early 1970's. Rather, they have varied with the swings in the business cycle, and the steady increases so evident in the 1960's have been absent. But the real incomes of *individual* Americans have continued to rise. While they too were affected by the economic slowdowns, real incomes of persons have pushed upward as they did in the 1960's. The question is: Why did these trends in real incomes diverge over the last decade and a half?

Family income data are collected every year in the Current Population Survey (CPS), conducted by the Bureau of the Census. Aggregate personal income is measured each month by the Commerce Department's Bureau of Economic Analysis (BEA), and can easily be converted into a per capita income series.[1] (Income data for individuals are also collected in the CPS and a per capita series from that survey is published by the Bureau of the Census.) Both the CPS family income data and the BEA personal income data are used extensively by economists for assessing the Nation's economic well-being. The difference in their trends in recent years is disturbing and raises questions as to what has happened to real incomes.

This article first discusses these divergent trends within the context of the economic setting and components from which they emerged. We then examine the concepts underlying each measure of real income and conclude with a reconciliation of the two. (A reconciliation of the BEA per capita series is also presented.) A technical appendix with tables is found at the end of the article.

The setting and the trends

The 1970's and early 1980's were years of significant economic, social, and demographic change. The recessions during this period caused millions of workers to lose jobs. Inflation eroded incomes, with particularly strong price increases occurring during the recessions. Along with these economic developments, profound social and demographic changes, begun years before, continued and intensified. Women joined the labor force in record numbers; the incidence of single-parent families increased as the divorce rate soared; the birth rate dropped further and population growth slowed relative to the 1960's; and the baby-boom generation flooded the labor market and sought its place in society. Because of these changes and a weak economy, governments struggled to help the poor, the unemployed, the medically needy, and others. Personal and family earnings were, therefore, frequently supplemented by transfer payments, such as unemployment insurance, aid to families with dependent children, and food stamps. Many of these changes affected BEA personal income and CPS family income differ-

Paul Ryscavage is a labor economist in the Population Division of the Bureau of the Census. The views expressed in this article do not necessarily represent those of the Bureau of the Census.

ently and caused their trends to diverge.

The divergence can be best observed when the BEA personal income series is converted into a per capita series. As shown in chart 1 and table 1, both the real BEA per capita income series and the real CPS family income series rose at an average annual rate of slightly more than 3.0 percent between 1960 and 1970.[2] In sharp contrast, real BEA per capita income continued to grow moderately, at a 1.8-percent rate, during the next 14 years while real CPS mean family income showed little growth—only 0.3 percent a year.

Differences in the levels of these two income series can be expected, of course, because one relates to the entire population and the other only to families. In 1984, for example BEA per capita income was $13,145 and CPS mean family income was $31,052. But differences in these series' trends of the magnitude that occurred in the 1970–84 period are unsettling, especially after they behaved so similarly during the 1960's.

Concepts and components

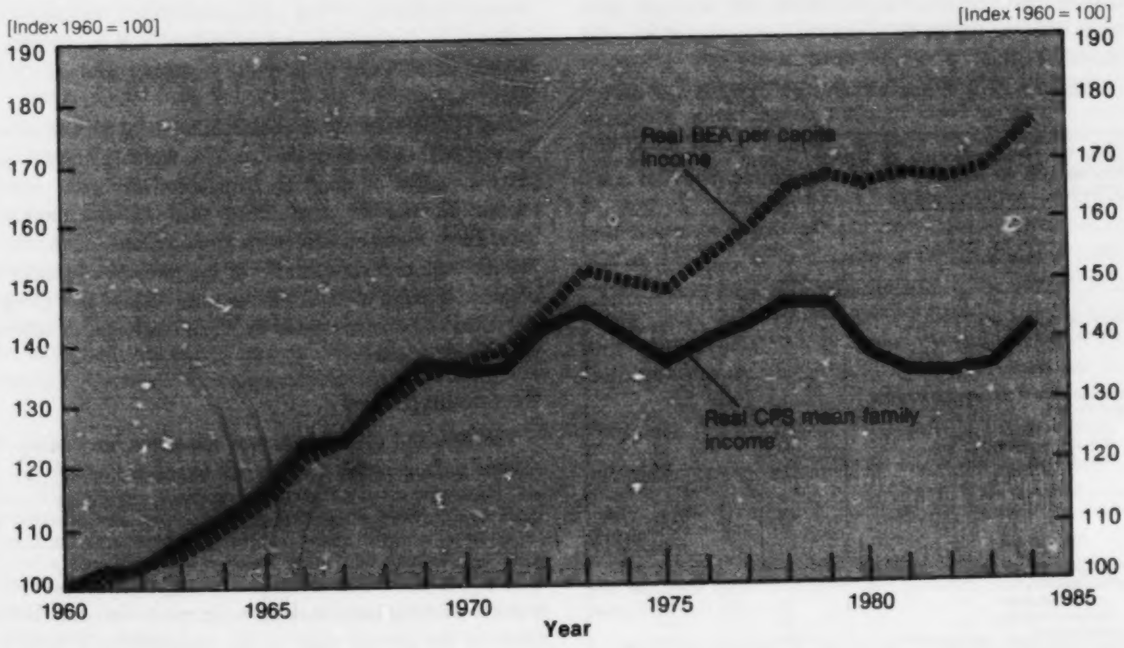
To understand why these real income measures diverged, it is important to understand the concepts behind them. As explained below, each measure has similar components, but conceptual differences exist between them.

Aggregate income. A major difference between the BEA and CPS income concepts is that BEA personal income relates to income from all sources, while CPS income relates only to money income.

The BEA series is developed from a variety of government statistics, the most important being the Federal tax records of the U.S. Department of the Treasury, the insurance files of the Social Security Administration, and the State unemployment records collected by the U.S. Department of Labor. Personal income comprises wages and salaries, including cash and in-kind payments; other labor income such as employer contributions to private pension, welfare, and workers' compensation funds; proprietors' income; the income from rental properties; dividends and interest; and government and business transfer payments (Social Security, food stamps, corporate cash prizes, and so forth). The sum of all these items minus the amounts paid by individuals for old age, survivors, disability, and health insurance (OASDHI), government retirement, and other social programs equals BEA's aggregate personal income.[3]

The CPS series is based on a sample of about 60,000 households designed to represent all households in the country. Each March, Census Bureau interviewers ask household respondents about their money income in the previous year. Important nonmoney income items excluded from the CPS

Chart 1. Indexes of real BEA per capita income and real CPS mean family income, 1960-84



series but included in the BEA series are wages received in-kind, food stamps, medicare and medicaid, the net rental value of owner-occupied homes, goods produced and consumed at home, and various fringe benefits provided by employers, such as health insurance and pension plans.[4] Most of the other income items reported in the BEA data are also collected in the CPS—money wages and salaries, self-employment income, interest and dividends, rental income, Social Security, cash transfer payments, and so on—but because this information is obtained from a sampling of households, a certain amount of income underreporting occurs.[5]

Price deflators. Another important conceptual difference between the BEA real income series and the CPS series concerns the price deflators used to convert nominal incomes into real incomes.[6]

CPS family income is converted into real dollars using the Consumer Price Index (CPI) produced by the Bureau of Labor Statistics. The CPI is obtained through direct price collection and measures price changes for a fixed market basket of goods and services (established in the 1972–73 period) that represents the average expenditures of urban consumers. BEA personal income is deflated by the implicit price deflator for personal consumption expenditures, hereafter referred to as the PCE Deflator. The weights for the commodities priced in this index are obtained in the period for which the index is to be computed. The PCE Deflator, unlike the CPI, is obtained by dividing current consumer expenditures by real, or constant dollar, expenditures. (To deflate current consumer expenditures, the BEA uses price indexes from the CPI for 85 of the 115 commodities included in the PCE Deflator.)

During the 1970's, many analysts suggested that the CPI was overstating the inflation rate when compared to the PCE Deflator. It was true that the homeownership component of the CPI (which consisted of house prices, mortgage interest, and the cost of maintaining a house) was very sensitive to the activity in the housing market and the wildly fluctuating mortgage interest rates. After a review of its pricing of homeownership, BLS concluded that its approach had investment and consumption aspects which were inconsistent with the principle that the CPI should focus only on current consumption. BLS therefore began experimenting with a rental equivalence approach—one similar to the one used in the PCE Deflator—and eventually adopted it beginning with publication of the January 1983 CPI.

Table 1. Reconciliation of trends in real BEA per capita income and in real CPS income measures, 1960–70 and 1970–84

Series and reasons for differences	Average annual rate of change (in percent)[1]	
	1960–70	1970–84
Real BEA per capita income	3.2	1.8
Real CPS family income	3.1	0.3
Total difference	0.1	1.5
Percentage points of difference due to varying growth rates in:		
Aggregate incomes	–0.1	0.8
Number of recipients	0.1	0.3
Price deflators	0.1	0.4
Real BEA per capita income	3.2	1.8
Real CPS per capita income	3.1	1.4
Total difference	0.1	0.4
Percentage points of difference due to varying growth rates in:		
Aggregate incomes	0.0	0.1
Number of recipients	0.0	–0.1
Price deflators	0.1	0.4

[1] See text footnote 2.

Table 2. Changes in components of BEA personal income and CPS family income estimates, 1960–70 and 1970–84

Year or period	Aggregate income (billions of dollars)		Income recipients (thousands)		Income deflator	
	BEA personal income	CPS family income	BEA population estimate	CPS family estimate	PCE Deflator (1982=100)	Consumer Price Index (1967=100)
1960	$ 409.4	$ 283.6	180,760	45,539	32.9	88.7
1970	831.8	580.0	205,089	52,227	42.9	116.3
1984	3,111.9	1,947.1	236,731	62,706	108.2	311.1
Average annual percent change:[1]						
1960–70	7.1	7.2	1.3	1.4	2.7	2.7
1970–84	9.4	8.7	1.0	1.3	6.6	7.0

[1] See text footnote 2.

Income recipients. The income recipients, of course, are different in the BEA per capita income and the CPS family income series. One relates to the population and the other to families.

BEA per capita income is calculated using an annual estimate of population from the CPS. This annual estimate represents averages of quarterly population estimates and includes inmates of institutions and military personnel overseas or living on post in the United States. In the family income measure, an estimate of the number of families is obtained through the CPS. Families are defined as a group of two or more persons related by birth, marriage, or adoption who reside together.

Reconciling trends

The BEA and CPS real income measures are constructed similarly. In general, they can be expressed as:

$$\overline{Y} = \frac{Y}{N \times D}$$

where $\overline{Y}$ is real mean income; Y is aggregate income; N is number of recipients; and D is the price deflator. Differences in the growth rates of the components in both real income measures were responsible for the divergent trends in real income. Indeed, it will be shown that these differences approximately equal the overall trend differences between the measures.[7] (See the appendix for a description of the reconciliation method.)

As indicated, the difference in annual growth rates in the per capita and family income series in the 1970–84 period was 1.5 percentage points. Based on the reconciliation method used in this article, about half of the trend difference, or 0.8 percentage points, was caused by different rates of growth in the aggregate incomes used in each series. Another 0.4 percentage points was the result of differential growth rates in the price deflators—the CPI and PCE Deflator—of the series. And the remaining difference of 0.3 percentage points was due to different growth rates in population and in number of families. (See table 1.) These differences are examined in detail below.

Aggregate incomes in the BEA per capita series and the CPS family income series grew at about the same average annual rate in the 1960's, but between 1970 and 1984, the BEA aggregate rose by 9.4 percent a year, compared to an 8.7-percent growth rate in the CPS aggregate (table 2). Two factors may have been responsible for the faster growth in BEA aggregate income. First, nonmoney income (such as food stamps, medicare, medicaid, and certain fringe benefits) grew rapidly in recent years, and much of the growth occurred in nonfamily households. (As mentioned earlier, nonmoney income is included under the BEA income concept, but excluded in the CPS concept.) Second, BEA aggregate income growth was also boosted by the maturing of the baby-boom generation. Many of the individuals from this group have not married, preferring to live alone or with other unrelated individuals. (The number of unrelated individuals age 25 to 34 grew from 1.8 million in 1970 to 7.3 million by 1984.) Their income is included in the BEA aggregate, but excluded from the CPS family income aggregate.

Table 2 shows that both the PCE Deflator and CPI measured inflation at the same annual rate during the 1960's—2.7 percent. Over the 1970–84 period, however, the CPI recorded a slightly faster increase in consumer prices than did the PCE Deflator, with the largest annual differences occurring in the late 1970's and early 1980's. The homeownership component of the CPI was greatly affected by the activity in the housing and money markets, and analysts have identified this component as responsible for the disparate inflation rates.[8] Consequently, use of the PCE Deflator in the BEA series would, other things equal, have less of an eroding effect on income than would the CPI in the CPS family income series.

Differences in the rates of growth of the Nation's population and families also affected the trends. As presented in table 2, the BEA estimate of population growth and CPS estimate of growth in numbers of families were very similar in the 1960–70 period—about 1.3 to 1.4 percent. But between 1970 and 1984, the number of families continued to grow by about 1.3 percent a year while population growth slackened to a 1.0-percent rate.

BEA and CPS per capita income. Income data are also collected for individuals in the CPS, and this information is published at the same time as the family income data.[9] The level of CPS real per capita income is slightly lower than the BEA estimate (as shown in appendix table A-3) because the CPS aggregate income estimate is less inclusive than the BEA estimate. Both series exhibited similar trends in the 1960's but then diverged slightly toward the end of the 1970–84 period. As shown in table 1, the trend difference was 0.1 percentage points a year between 1960 and 1970, but then widened to 0.4 points annually between 1970 and 1984. According to the reconciliation methodology used in this article, all of the difference in the growth rates of these two series was caused by the different price deflators. As mentioned earlier, the CPI rose much faster than the PCE Deflator at the end of the 1970's and beginning of the 1980's.

THE DIVERGENT TRENDS in real BEA per capita income and real CPS family income between 1970 and 1984 are reconcilable. Each measure reflected the economic, social, and demographic changes of the period to the extent that its concepts and components allowed. And this illustrates an important point: During times of rapid economic, social, and demographic changes, a single income measure may give a less than complete picture of what has happened because of the way in which it is constructed. In the case just discussed, a global measure of real income indicated that real incomes were rising in the 1970's and 1980's, while a narrower measure showed little growth taking place. Once the concepts and components of each measure were understood, however, it could be shown that both trends were compatible. □

FOOTNOTES

[1] BEA publishes a series on per capita "disposable" income (personal income minus tax and nontax payments, divided by the population). The population estimates used in that series were used in deriving the per capita personal income series discussed in this article. Statistics on per capita personal income have been published before. For example, see *Social Indicators III* (Bureau of the Census, December 1980), pp. 474–75.

[2] The average annual rates of change in this report have been calculated by the following formula:

$$r = \ln \frac{P_1}{P_0} \div N \times 100$$

where *ln* is the natural logarithm of the ratio; P_1 is a number at the end of some time interval; P_0 is a number at the beginning of the interval; N is the number of years in the interval; and r is the average annual rate of percent change.

[3] For a thorough discussion of the BEA income concept, see *Business Statistics 1979* (U.S. Department of Commerce, Bureau of Economic Analysis, 1981).

[4] For a full discussion of the CPS money income concept, see *Money Income of Households, Families, and Persons in the United States: 1983*, Current Population Reports, Series P-60, No. 146 (Bureau of the Census,

1985), pp. 207–19.

[5] In 1983 (the last year for which such data are available), the CPS collected 90.1 percent of an independent estimate of aggregate income adjusted to the CPS money income concept. See *Money Income of Households*, p. 219.

[6] The discussion in this section is based on two articles: Jack E. Triplett, "Reconciling the CPI and the PCE Deflator," *Monthly Labor Review*, September 1981, pp. 3–15; and Robert Gillingham and Walter Lane, "Changing the treatment of shelter costs for homeowners in the CPI," *Monthly Labor Review*, June 1982, pp. 9–14.

[7] The same methodology was used by the author in reconciling trends in real per capita disposable income and real net spendable earnings. See Paul Ryscavage, "Two divergent measures of purchasing power," *Monthly Labor Review*, August 1979, pp. 25–30.

[8] Triplett, "Reconciling the CPI and PCE Deflator," p. 4.

[9] *Money Income of Households*, p. 121.

APPENDIX: Reconciliation method

The method used to reconcile the trends in real BEA per capita income and real CPS mean family income proceeds as follows. Let the change in real BEA per capita income be defined as:

$$\frac{\overline{Y}_1}{\overline{Y}_0} = \frac{\dfrac{Y_1}{N_1 \times D_1}}{\dfrac{Y_o}{N_o \times D_o}}$$

where in periods 0 and 1, $\overline{Y}$ equals real per capita income, *Y* the aggregate personal income, *N* the population of recipients, and *D* the implicit price deflator for personal consumption expenditures. This expression can then be written as:

$$\frac{\overline{Y}_1}{\overline{Y}_0} = \frac{Y_1}{Y_0} \times \frac{N_0}{N_1} \times \frac{D_0}{D_1}$$

Table A-1. Components of the real BEA personal income per capita series, 1960–84

Year	Real BEA per capita income (1982 dollars)	BEA per capita income	BEA aggregate personal income (billions)	BEA population[1] (thousands)	PCE Deflator (1982=100)
1960	$ 6,884	$ 2,265	$ 409.4	180,760	32.9
1961	6,961	2,318	426.0	183,742	33.3

Year	Real CPS mean family income (1984 dollars)	CPS mean family income	CPS aggregate family income (billions)	Families (thousands)	Consumer Price Index (1967 = 100)
1960	$21,840	$ 6,227	$ 283.6	45,539	88.7
1961	22,468	6,471	300.4	46,418	89.6
1962	22,903	6,670	313.9	47,059	90.6
1963	23,741	6,998	332.7	47,540	91.7
1964	24,587	7,336	351.8	47,956	92.9
1965	25,362	7,704	373.7	48,509	94.5
1966	26,869	8,395	413.2	49,214	97.2
1967	27,380	8,801	441.0	50,111	100.0
1968	28,871	9,670	491.5	50,823	104.2
1969	29,968	10,577	545.6	51,586	109.8
1970	29,708	11,106	580.0	52,227	116.3
1971	29,707	11,583	617.3	53,296	121.3
1972	31,346	12,625	686.5	54,373	125.3
1973	31,839	13,622	749.9	55,053	133.1
1974	30,986	14,711	819.4	55.698	147.7
1975	30,002	15,546	874.4	56,245	161.2
1976	30,782	16,870	956.7	56,710	170.5
1977	31,305	18,264	1,045.0	57,215	181.5
1978	31,987	20,091	1,161.3	57,804	195.4
1979	31,934	22,316	1,328.9	59,550	217.4
1980	30,220	23,974	1,445.8	60,309	246.8
1981	29,509	25,838	1,576.6	61,019	272.4
1982	29,475	27,391	1,681.6	61,393	289.1
1983	29,826	28,608	1,774.1	62,015	298.4
1984	31,052	31,052	1,947.1	62,706	311.1

Taking the natural logarithms of each side yields the following equation:

$$\ln\frac{\overline{Y}_1}{\overline{Y}_0} = \ln\frac{Y_1}{Y_0} + \ln\frac{N_0}{N_1} + \ln\frac{D_0}{D_1}$$

and when the deflator and recipient components are inverted for the purpose of the reconciliation, the equation becomes:

$$\ln\frac{\overline{Y}_1}{\overline{Y}_0} = \ln\frac{Y_1}{Y_0} - \ln\frac{N_1}{N_0} - \ln\frac{D_1}{D_0}$$

The same procedure is used with real CPS family income, and for the purposes of this description, components are notated in the same, but lower case, letters. That is, $\overline{y}$ equals mean family income, *y* the aggregate family income, *n* the number of families, and *d* the Consumer Price Index (CPI). Consequently, the difference in growth rates between real

Table A-3. Components of the real CPS per capita income series, 1960–84

Year	Real CPS per capita income (1984 dollars)	CPS per capita income	CPS aggregate income (billions)	CPS population[1]	Consumer Price Index (1967 = 100)

1982	9,863	8,980	2,061.7	229,587	289.1
1983	9,954	9,548	2,214.5	231,938	298.4
1984	10,328	10,328	2,417.4	234,066	311.1

[1] The population estimates are as of March of the following year. They represent the civilian noninstitutional population plus the Armed Forces personnel living off post or with their families on post in the United States.

BEA per capita income and real CPS mean family income is:

$$\text{DIFFERENCE} = \ln\frac{\bar{Y}_1}{\bar{Y}_0} - \ln\frac{\bar{y}_1}{\bar{y}_0}$$

or

$$\text{DIFFERENCE} = \ln\frac{Y_1}{Y_0} - \ln\frac{N_1}{N_0} - \ln\frac{D_1}{D_0} - \ln\frac{y_1}{y_0} + \ln\frac{n_1}{n_0} + \ln\frac{d_1}{d_0}$$

The terms in the above expression can be rearranged to define the following effects, all of which approximately add to the difference in growth rates between the real income measures:

$$\text{Aggregate income effect} = \ln\frac{Y_1}{Y_0} - \ln\frac{y_1}{y_0}$$

$$\text{Recipient effect} = -\ln\frac{N_1}{N_0} + \ln\frac{n_1}{n_0}$$

$$\text{Deflator effect} = -\ln\frac{D_1}{D_0} + \ln\frac{d_1}{d_0}$$

Appendix tables A-1, A-2, and A-3 contain the basic data to which this reconciliation method was applied.

Keeper of the gate

Ellis Island a welcome site? Only after years of reform

With the reopening of the immigration center as a historic landmark, it may surprise many to learn that the Labor Department operated the complex for years; administrators struggled to end corruption and the exploitation of aliens

HENRY P. GUZDA

Between 1903 and 1920, 10 million people emigrated to the United States by passing through the portals of the receiving station on Ellis Island. During that period, the U.S. Department of Labor and its predecessor agency, the Department of Commerce and Labor, administered the immigration laws of the country, including those providing for the operation of Ellis Island.

The island lies just a short distance from the New Jersey shoreline in New York Harbor. The Federal Government, over many years, expanded the land area from 7.5 acres to a landfilled 27.5 acres for new buildings, park areas, and other facilities. The main hall, a spacious brick building with white limestone trim, in French Renaissance style, is the most striking landmark on the island and the site where immigrants first entered for processing. Kitchen facilities, dormitories, a hospital, and a power plant also occupied island space. Docks to receive passenger and cargo vessels expanded in proportion to the island's growth.[1]

Men, women, and children segregated by sex, stood in lines on Ellis Island awaiting a barrage of questions on their potential destinations, intentions for going there, and job prospects upon arrival. Prearranged labor contracting was illegal and would mean deportation. Inspectors often had limited comprehension of certain languages, especially Slavic ones, and misinterpretations were common. The newcomers faced assembly-line medical exams and if doctors or nurses put certain chalk letters on an immigrant's outergarment it meant detention and possible deportation. (The letter T signified suspected trachoma, H meant a possible heart condition, and LCD translated as loathsome contagious disease. Nonmedical examiners could put LPC (likely to become a public charge) on a person's coat, which also could result in deportation.) One of the island's Public Health Service physicians commented, "these methods, crude as they seem, had to be used because of the great numbers [of immigrants] and the language difficulties."[2]

Detention could last weeks, even years in wartime. During detention the immigrants fell prey to the avarice of contractors handling food concessions, money exchanges, and other personal services. Federal employees of Ellis Island extorted money from detained immigrants by threatening them with deportation. Finally, a special board of inquiry determined whether a detainee was admissible or deportable, the latter was subject to approval by the Secretary of Labor. It was not incomprehensible why the immigrants referred to Ellis Island as the "Isle of Tears."

Processing millions of people, however, was a tedious and taxing chore. The Labor Department and Public Health

---

Henry P. Guzda is an industrial relations specialist, Bureau of Labor-Management Relations and Cooperative Programs, U.S. Department of Labor, and was formerly a historian with the Department.

Service employees, grossly understaffed and overworked, faced difficult problems even during the ebb of immigration. During the peak year of 1907, an average 5,000 immigrants arrived daily and 11,747 landed on a recordbreaking day. Inspectors with command of certain languages were in demand, but the supply was always low. To compound these problems, the immigration laws were complex—defying interpretation even by some legal authorities—yet only 1.5 percent of all immigrants were excluded.[3]

Commerce and Labor: the first 10 years

When the Department of Commerce and Labor assumed responsibility for administration of the island from the Treasury Department in 1903, it received a rather sordid legacy. Both the friends of immigration and those favoring immigration restriction viewed the islands operation as disgraceful. President Theodore Roosevelt, who created the Department of Commerce and Labor in 1903, wanted the agency to reform conditions without delay.

William Williams to lead. Roosevelt chose the new Commissioner of Ellis Island, William Williams, a corporation lawyer from New York. He was an unlikely choice because of his jaundiced views on immigrants from Southern and Eastern Europe.

But Williams was honest, humane, and very concerned about reports from undercover agents on the conditions allowed by the former commissioner, Thomas Fitchie. Those reports illustrated that the depth of graft and corruption extended from the immigrant inspectors, who extorted bribes from aliens, to aldermen at New York's City Hall, who performed marriage ceremonies for exorbitant fees and "kicked back" commissions to Fitchie. Graft was so well-woven into the administrative fabric of the island's operations that the undercover agents feared for their lives if exposed.[4]

Williams acted quickly; his first official order was for employees to treat immigrants with "kindness and decency" or face dismissal. Several workers were fired after they tried to remove information on the confinement and isolation of immigrants into "pens" from official files. Williams told the President that the term "pen" intimated the kind of treatment the immigrants received, and that Fitchie was aware of the abuse and exploitation.

The food concession on Ellis Island particularly upset the new commissioner. Williams reported:

> "I witnessed with my own eyes the fact that immigrants were often fed without knives, forks, or spoons, and I saw them extract boiled beef from their bowls of soup with their fingers . . . (the meat was tainted) and the floors were covered with grease, bones, and other remnants of food for days at a time."

He canceled the existing food contract and awarded one to a different firm at a savings of 15 percent. In his annual report Williams noted that such reforms were gratifying, "but that numerous other instances of abuses or lack of system could be cited."[5]

Table 1. Immigration to the United States through Ellis Island and all entry ports, 1903–24

Year	Ellis Island	All entry ports
1903	631,835	857,046

Total	10,988,270	15,739,135

SOURCE: Bureau of Immigration and Naturalization, Historical Study, 1935.

Reforming the deeply embedded corruption of many years took time, and it appeared too slow for some interested parties. Foreign language newspapers and immigrant aide societies, in particular, accused the Department of Commerce and Labor of countenancing exploitation of the immigrants. The *New York Staats Zeitung* so severely complained that Roosevelt appointed a special investigatory commission in September 1903. Its report illustrated that the drive for reform had taken hold very quickly. Buildings were clean and immigrants were well-fed, and treated with decency. Delays in processing functions and overcrowding resulted, the report concluded, from insufficient staffing and poor facilities, not mistreatment.[6]

By 1905, the island's operation ran very smoothly. Williams believed his job had been completed and returned to private law practice. Reforms continued, however, under his successor Robert Watchorn.

Robert Watchorn's administration. Watchorn, like many immigration officials, came from the labor movement, having served as an official of the United Mine Workers union. Unlike many of his labor colleagues, Watchorn was not an immigration restrictionist.[7]

Watchorn had a kindred spirit in Secretary of Commerce and Labor Oscar Straus. Straus, an immigrant and the first Jewish person to serve in a presidential cabinet, believed in an open-door policy for immigration. Whereas previous Secretaries of Commerce and Labor had viewed Ellis Island as an administrative headache, Straus took greater interest in immigration than his predecessors and gave full support to the views of the new commissioner.

The Straus-Watchorn tandem served during the "high tide" of immigration, 1905-09. In the peak year of 1907, 1.3

million people came to the United States. (See table 1 for immigration totals.) Delays in processing and admissions increased despite Watchorn's efforts to streamline operations. He abolished the "temporarily detained" category for immigrants suspected of a minor infraction of law or unable to produce a $10 minimum reserve before being allowed entry to the mainland. Steamship lines had to provide island officials with informational lists of all passengers before disembarking them. Nonetheless, immigrant inspectors worked 7 days a week from 9 a.m. to 9 p.m. for 31 consecutive days in which more than 5,000 persons arrived daily in 1907.[8]

Working conditions for Ellis Island employees worsened considerably during this period. The close proximity of so many people and unsanitary conditions on passenger ships, especially for the bulk of immigrants traveling in steerage, spread vermin and disease among both immigrants and Federal employees. To compensate for long hours and poor conditions, Watchorn petitioned the Congress to raise employees' wages, add staff positions, and appropriate funds for other morale-building efforts. But his endeavor was fruitless, and between 1905 and 1907 there was a turnover rate of approximately 40 percent. Immigration inspector Fiorello LaGuardia, who later became Mayor of New York, commented, "At best, the work was an ordeal. Our compensation, besides our salaries, for the heartbreaking scenes we witness (sic) was the realization that a large percentage of these people pouring into Ellis Island would probably make good and enjoy a better life than they had been accustomed to."[9]

Under Watchorn and Straus, general improvement in the prevention of immigrant exploitation accelerated. Watchorn assigned undercover agents to find abuses, and their reports confirmed his suspicions. For example, steamship companies made $39 of profit from the $42 charged to immigrants for transportation from Europe. Agents for employment services conducted an illicit business in contract labor and cooperated with both steamship lines and railroad interests to fleece the aliens. For example, one employment agent charged 50¢ for a short ride from the Ellis Island debarkation point to Grand Central Station and received an additional 45-cent commission for placing them on the New York, New Haven, and Hartford line, regardless of a passenger's actual destination. Railroads re-routed passenger service in order to maximize fares; immigrants bound for Chicago, therefore, often traveled a circuitous route through Norfolk, Virginia. "I am shocked and outraged," said Watchorn, "by the many pretexts resorted to by the opulent and powerful, and by petty grafters to squeeze the last dollars out of the immigrant in quest of work and wages. . . ." In 1907, Watchorn filed charges against railroad and steamship companies with the Interstate Commerce Commission and achieved some success in eliminating the worst abuses.[10]

Watchorn's crusade was noticed. Food contractors, transportation concerns, and employment agencies pressured Straus, the Congress, and President Roosevelt to remove the commissioner from office. In addition, organized labor complained that the new Ellis Island policies had swamped the U.S. work force with undesirables willing to work for below minimum wages. Even some Federal employees on Ellis Island protested that Watchorn had exceeded his authority by disregarding laws and longstanding work rules.[11] In response, Straus sent an investigatory commission to the island. This commission, headed by popular reformer and intellectual Washington Gladden, and consisting of other ministers and rabbis, found conditions to be exemplary. Gladden reported:[12]

> "I am sure that anyone who visits Ellis Island, and intelligently observes what is going on there; who sees the cleanliness and convenience and comfort by which the immigrants are surrounded when they first set foot upon our soil; the ample and beautiful dining room where good food is served to them; the commodious and comfortable sleeping apartments, the roof garden where, in the summer, they may breathe the cool air in the evening; the small army of intelligent and kindly men and women who speak to them in their own languages, and administer to all their wants; the vigilance with which they are safeguarded from the wolves and harpies which in former times were wont to make them a prey . . . I am sure that anyone who sees all this will feel that he has witnessed one of the triumphs of civilization."

Straus also ordered the Commissioner of Corporations to conduct an internal investigation of the island's operations. While not as ebullient and optimistic as the Gladden report, this study gave Watchorn and his administration a good rating. The facilities at the complex, it stated, were clean, sanitary, and well-organized. Watchorn, despite criticisms to the contrary, had deported more immigrants during his years than had Commissioner Williams and was not lax in law enforcement.[13]

Yet the very controversial nature of the immigration question eventually contributed to Watchorn's departure. His former colleagues in the labor movement vehemently opposed "open door" immigration policies, including redistribution of immigration away from labor surplus areas on the eastern seaboard and in the industrial north. Watchorn tried to explain that redistribution could work, at a Labor Department conference on the immigration issue, but ran into criticism from his agency associate, Commissioner of Labor Charles Neill, who argued that the plan wouldn't work.[14]

Such controversy illuminated the serious impediments to a reconfirmation of Watchorn as commissioner. Straus engaged an intensive campaign to have his friend reconfirmed. The Immigrant Protective League and other ethnic organizations joined the campaign, but there were just as many groups, the American Federation of Labor, for example, that opposed a second term. On March 4, 1909, the newly inaugurated President, William Howard Taft, withdrew Watchorn's name from consideration.[15]

Williams returns. Taft's Secretary of Commerce and Labor, Charles Nagel, also chose to avoid controversy by persuading William Williams to return as Ellis Island Commissioner in the role of a compromise appointment.

Williams' second term paralleled the first and mirrored that of Watchorn's in attacking corruption. For example, in December 1910, he had the Hellenic Transatlantic Steamship Company prosecuted for willfully smuggling diseased aliens through the island and attempting to bribe immigration officials; 15 company officials went to jail as a result. Williams also withdrew privileges for operating services on the island from some immigrant aid societies which ran unclean boarding houses on the mainland. Thus, Williams received criticism from both sides of the immigration question. Ironically, despite his own restrictive beliefs, he was criticized for lax administration of the immigration laws. Williams voluntarily resigned in 1913, leaving a fairly well-run and efficient operation.[16]

New problems

As World War I erupted in 1914, an ideological movement swept across the United States. Racial and ethnic stereotyping and eugenics were popularly discussed as an exact science. The president of the New York Zoological Society, Madison Grant, published *Passing of the Great Race*, which called for "Nordic supremacy;" Grant compared old immigration from Northern and Western Europe to the strong species of the animal kingdom and relegated new immigration from Southern and Eastern Europe to the weakest species. In addition, Majority Whip Harold Knutson complained about the "mongrelizing" effect the new immigration had on American society and the Eugenicist for the Congressional Committee on Immigration, Harry Laughlin, theorized that the recent immigration possessed a high percentage of inborn socially deviant qualities based on empirical data.[17]

These attitudes were prevalent when the newly created Department of Labor assumed responsibility for Ellis Island in 1913. The labor function in the Department of Commerce and Labor had been secondary in the organization and many interests, especially Samuel Gompers and the American Federation of Labor, wanted it removed and elevated to Cabinet status without nonrelated encumberances. Organized labor did not particularly want the immigration function placed in the Department of Labor but believed it could be monitored better under friends than in the employer-oriented Department of Commerce.[18]

The first Secretary of Labor, William B. Wilson, a longtime official of the United Mine Workers union, however, did not have the animus toward immigrants held by many labor leaders. His Commissioner of Ellis Island, Frederick C. Howe, was a philosophical ally of Robert Watchorn. While Howe did not have views concurrent with some other Labor Department officials, including his immediate superior Commissioner General of Immigration Anthony Caminetti, he had the support of Wilson and Assistant Secretary of Labor Louis Post.

Frederick C. Howe's efforts. Howe's goal was the complete "humanization" of Ellis Island. The temporary occupants of the station, he said, were human beings, not digits in an annual report. He ordered the employees of the island to treat immigrants with respect and, as one of his first acts, ordered the construction of playgrounds for children and opened restricted grassy areas for adults. His two predecessors, Howe noted, had done a fine job improving conditions of Ellis Island, and now it was time to refine their efforts. But World War I immediately altered his plans.[19]

The war severely restricted the flow of immigration. By late 1915, the island's staff faced a turnabout in their work environment. Almost 900,000 people passed through the island during fiscal year 1914, but the number declined to less than 200,000 in 1915 and to less than 30,000 by 1919. During the harsh winter of 1915, Howe provided sleeping quarters on the island to the indigent of New York, but this did not affect the staff. The previously overworked employees now faced Federal reductions-in-force. Howe complained that personnel reductions were harmful and would impair efficiency by decreasing morale. The previously excessive workloads would become normal because of a slack in immigration, he said, so the staff levels should be maintained. "Should immigration materially increase (following the war)," he told Secretary Wilson, "it will require considerable time to restore the staff operations to its former degree of efficiency." Immigration remained low until 1919, but personnel cutbacks resulted in Howe working many of the 400-person staff (650 was the pre-war level) overtime and in functions unfamiliar to employees.[20]

One of the war-related problems was that the island became a domicile for detained and potentially deportable immigrants unable to return to their conflict-ridden homelands. Detention periods extended from weeks to years, and Howe ordered the creation of schools and recreational areas. When some immigration employees protested that the grass and shrubs would be ruined, Howe answered that live babies took precedence over live grass. Buildings received fresh coats of colorful paint and plants were hung in all buildings; some members of the press criticized Federal expenditures for plants until they discovered Howe had paid for them from his own salary.[21]

Special efforts were made to provide for a healthy environment. Island staffers coordinated immigrant recreational events such as baseball games and sewing bees. Immigrant benevolent societies arranged for ethnic celebrations: and Americanization themes dominated events such as patriotic concerts. Immigrant children competed in essay contests describing the American way of life and were rewarded by raising the American flag in special ceremonies. Mrs. Harry Payne Whitney, of Whitney museum fame, donated over 30 paintings and statuary depicting immigrant contributions to America to adorn the grounds and the buildings of Ellis Island.[22]

Critics asked why the Ellis Island commissioner devoted so much time and effort to Americanize potentially deportable immigrants? Howe answered them by releasing some detainees labeled "likely to become a public charge" to sponsors on the mainland providing homes and employment. He conducted similar "work-release" programs for women charged with "moral turpitude," believing that such crimes were the results of poverty and lack of opportunity, not innate proclivities. In one 18-month period, only 6 of 340 people released had failed the program and other release groups had similar success ratios.[23]

Howe also tried to improve conditions for the Federal employees of Ellis Island. He persuaded the Secretary of Labor to give promotions to deserving employees and arranged for a guest lecture series for the staff; Secretary Wilson and former President William Howard Taft were among the speakers in this forum. Howe also published a series of articles on the competency and integrity of the workers at the complex. "I have never known a group of 500 men and women," he said in one article, "either in public or private work, who were more devoted to their employment or more willing to be of personal service than the government employees stationed at Ellis Island."[24]

Efforts turn to controversy. It was the promotion of Howe's own employees over the interests of private contractors that engulfed him in a major controversy. The private concession for feeding immigrants and operating the public restaurant on Ellis Island had been a source of anguish to all commissioners. When the contract for Hudgins and Dumas Co. expired in 1916, Howe did not renew it, operating the concession "in house" with Federal employees. The constant temptation for contractors to reduce food quality and quantity, he said, made such an action necessary. This step, however, aroused much protest from New York businessmen and especially from Congressman William Bennet, a former attorney for Hudgins and Dumas. Secretary Wilson feared a major political problem would develop and ordered Howe to award a contract to a concessionaire.[25]

This was not the sole controversy of Howe's administration. Many immigrants were taken advantage of by employment agents, transportation companies, boardinghouse operators, and other commercial interests. Howe proposed the creation of an Immigration Bureau to oversee the process of relocating aliens away from congested labor surplus areas. Even though he only got an immigration information division similar to the one Robert Watchorn created, it raised protest from businessmen who earned considerable profit from the immigration trade. When Howe broke up a pooling arrangement between steamship lines and railroads, stating, "immigrants should not be sent around Robin Hood's barn because the railroads decreed no single road should get the bulk of traffic," it spawned a letter-writing campaign to the Congress for his removal. Howe also disguised Federal employees as immigrants and uncovered fraud of up to $12 million propogated by area bankers; this, of course, drew the wrath of the less than honest members of the financial community.[26]

Cries for Howe's removal escalated inversely to the level of world-wide conflict. As the war waned, his critics, especially steamship lines, increased pressure on their lobbyists to persuade the Congress to restrict the commissioner's activities. Some officials of several steamship lines even paid an immigrant woman $500 to accuse Howe of engaging in illicit relationships with her and other immigrant women on Ellis Island. Secretary Wilson investigated and found all such charges against Howe were false, but pressure for removal from office did not abate until he resigned in September of 1919—10 months after the war terminated.[27]

Several other problems plagued the administration of Ellis Island during and after Howe's departure. On July 30, 1916, German saboteurs dynamited a munitions storage area near the island, and, while the only serious casualty of the "Black Tom Explosion" was a cat, property damage to the buildings and grounds was extensive. The military commandeered part of the complex to detain prisoners of war following America's entry into the conflict in 1917, and the detainees, confined to overcrowded facilities, conducted several mini-riots in protest. Conditions deteriorated to the point that the local chapter of the National Federation of Federal Employees filed an official protest over wage and working conditions with Howe's successor, Acting Commissioner Byron Uhl. Soon afterward, Secretary Wilson told Assistant Secretary Louis Post and Immigration Commissioner General Anthony Caminetti to "visit Ellis Island and clean up the mess."[28]

Immigrant radicals

With the end of World War I came one of the most controversial and notorious events in the history of civil rights, and Ellis Island was an integral part of the drama. War hysteria, fueled by yellow journal newspapers and eugenical publications, promoted the postwar phenomenon called the "red scare." The ghost of Bolshevism seemed, to many Americans, to haunt the land in the specter of immigrant radicals, especially after the 1919 wave of industrial unrest in immigrant-dominated work forces of the coal, steel, meatpacking, and transportation industries. In 1919, an anarchist placed a bomb on the doorstep of Attorney General A. Mitchell Palmer, and, while the blast's only victim was the would-be terrorist, it sparked Palmer and his assistant, J. Edgar Hoover, into a crusade to deport all alien "reds."

Department of Justice marshals swept into immigrant union halls, fraternal society meeting houses, dance halls, and saloons, arresting aliens en masse, often without warrants or concern for due process, under Palmer's orders. While Howe was commissioner only 60 of the 697 arrested aliens were actually deported for willful advocacy of the overthrow of the Federal Government (including membership in the Communist Party). But when Howe was away, and again after his departure, Acting Commissioner Uhl and Commissioner General Caminetti enthusiastically assisted the Justice Department. Ellis Island became a jail for the potential deportees and disembarkation point for shipment overseas.[29]

A heated political and administrative conflict occurred when Justice Department and Labor Department leaders interpreted the immigration laws differently. Secretary of Labor Wilson and Assistant Secretary Post believed the laws, which denied juridical rights to aliens and left their fate in the administrative hands of the Secretary of Labor, were poorly written and ambiguous. They believed that aliens should only face deportation if they openly advocated violent overthrow of the Government. Justice officials viewed membership in a radical organization as a deportable offense. When these officials arrested and scheduled deportation for more than 300 aliens in December 1919, Wilson, who believed some of the detainees were deportable, ordered a stay of deportation for aliens having families (who could not be deported even voluntarily under the immigration laws). All aliens arrested and taken to immigrant stations other than Ellis Island were spared, but Uhl, collaborating with Palmer and Hoover, ignored his superior's order and allowed 249 persons, including anarchists Emma Goldman and Alexander Berkman, to be deported.[30]

Apparently encouraged by their success, Hoover and Palmer ordered a massive arrest program in January 1920. Thousands of aliens, many of whom had attained U.S. citizenship, were arrested without warrants and placed in temporary jails to await transportation to Ellis Island. Immigration Commissioner Caminetti approved of *ex post facto* warrants and held special boards of inquiry to process deportation papers without notifying the Secretary of Labor, with whom responsibility for such a procedure rested.

After Wilson became ill, Assistant Secretary Post took immediate steps to correct the illegal and unethical actions of his subordinate. He ordered Caminetti to forward all cases to him and release all detainees on bail until the review process was complete. Post also told J. Edgar Hoover to cease interrogating aliens detained at Ellis Island unless approved by an official board of inquiry sanctioned by the Secretary of Labor or himself. Immigration officials, citing lack of evidence and a low percentage of "guilty" findings of those arrested previously, began refusing warrant requests from Justice officials.[31]

This battle between the two departments continued into the summer of 1920, but it was clear that the Labor Department would not let Ellis Island become a court of star chamber. When Attorney General Palmer ordered his agents to censor the mail of detained aliens on Ellis Island, Labor Department Solicitor Rowland B. Mahany informed him that censorship in peacetime would not be tolerated. Palmer withdrew all but a token force of agents from Ellis Island and other immigrant stations. By mid-1920 the "red scare" had abated, and Post, who faced a Congressional impeachment hearing for his stand against injustice, commented, "We have been going through a state of hysteria. Folks will look back with regret for having made fools of themselves, but there is nothing like a panic to make fools of us all."[32]

Restrictions begin, Island closes

Historian John Higham contends that the notion of 100 percent Americanism emerged from World War I and manifested itself in measures to restrict immigration. Ellis Island witnessed an immediate surge in postwar immigration, but soon afterward experienced a decline attributable to xenophobia. President Woodrow Wilson pocket-vetoed an immigration restriction bill in February 1921; however, the Congress reintroduced and passed it in April. President Warren G. Harding signed the Quota Act of 1921 into law on May 19th. The new Secretary of Labor, James J. Davis, approved of restrictive ideology stating, "I would say that the regulation of immigration is about the most important (issue facing him)". Davis even wrote a book entitled *Selective Immigration* in which he lamented the "mongrelizing" influences on American society wrought by the new immigrants.[33]

But the Quota Act of 1921 would have affected Ellis Island regardless of the philosophical leanings of the Secretary of Labor. It limited the number of foreign nationals allowed entry to 3 percent of their compatriots in the United States, according to the census of 1910; no more than 20 percent of the admissible number could arrive in a single month. The Quota Act of 1924 limited the number further by basing entry quotas on the census of 1890, when even fewer immigrants from Eastern and Southern Europe lived in the United States. Ellis Island assumed the role of a detention center for potential deportations more than of an entry-processing center because immigrant inspections began to occur to an increasing degree in Europe, and also because of the policies of the next Secretary of Labor, William N. Doak (1930–33). Doak so intently wanted to relieve the United States of a perceived foreign menace that he resurrected the Hooverian practice of mass arrests and deportations; this earned for Doak the nicknames "Secretary of Sedition" and "Deportation Chief." While several thousands of immigrants still passed through the station at the Port of New York, totals would never again approach those of 1903–14. And, conditions on the island during the Doak-Depression years reverted to those of the corrupt Fitchie administration, not to improve until 1934. In 1940, the responsibility for administering the immigration laws was transferred to the Department of Justice along with the responsibility for Ellis Island.[34]

The days of massive immigration, however, had passed. Ellis Island served its primary function for only 14 more years, and decay and disrepair had already set in when the doors closed in 1954. But the new historic site has generated considerable attention and enthusiasm; plans for reenactments of the immigrant experience—living history—have already been formulated. The administrative and institutional details of that experience, one hopes, will not be lost, and the roles played by both the Department of Commerce and Labor and the Department of Labor will not be forgotten. □

Conventions

Communications Workers focus on bargaining with AT&T

STEVEN M. DONAHUE

With the theme, "we're union, family, and proud," and promises that no concessions will be given to profitable companies, the Communications Workers of America (CWA) met in Washington, DC, for their 48th annual convention. Convention activities centered on current and pending negotiations, organizing, the union's finances, and the election of officers. In most of these actions, the influence of CWA's Committee on the Future and the effects of corporate divestiture were apparent. Gaveling the convention to order for the first time was Morton Bahr, who replaced Glenn Watts as president when the latter retired in 1985.

Bargaining. For the CWA, 1986 will be filled with critical bargaining activity. For the first time, the union will negotiate with an American Telephone and Telegraph Co. (AT&T) divested of its operating arms, which have become the Regional Bell Operating Companies. Also scheduled for negotiations are agreements at the General Telephone Co. subsidiaries across the United States, the ALLTEL system, four units of the Continental System, and public sector workers in a number of States, most importantly, New Jersey.

AT&T negotiations began April 2 after the union and the company agreed to move the scheduled August 9, 1986, contract expiration date to May 31. Expiration of the Regional Bell Operating Companies' contracts will remain August 9. President Bahr noted that the early negotiations at AT&T ". . . allow us to concentrate our resources and energies on these talks so that in turn, we can focus better on the task of bargaining with the Regional Bell companies later on." In support of bargaining, the Executive Board authorized the transfer of $1 million from the general fund to the defense fund, permitting Communication Workers to strike June 1 in the event an agreement is not reached. The negotiations will be conducted on behalf of 155,000 employees. In concurrent bargaining, the International Brotherhood of Electrical Workers will represent an additional 40,000 workers, making this round of negotiations the largest single-employer talks to be held during 1986.

Negotiations with General Telephone began in March at General of California and will continue through December at nine other sites. At ALLTEL, another independent system, talks also run through the end of 1986, while bargaining with the four units of Continental will take place in September and November.

Citing increased profits and continued growth in the telecommunications industry, in particular, at AT&T and the regionals, Bahr told the convention that the union will seek a base wage increase and will oppose a two-tiered wage structure. In the California negotiations with General Telephone, union leaders rejected a two-tiered proposal that would have downgraded jobs held predominantly by women. In the AT&T negotiations, said Bahr, the union's goal is to obtain a fair settlement which would also keep the company financially healthy without the need for a two-tiered wage structure. In justification, Bahr noted that telecommunications worker productivity had increased at an average rate of 6 percent per year for the past 10 years, a period when U.S. industry overall experienced negative productivity growth rates. In addition, he cited financial reports which stated that AT&T had net profits of $1.56 billion in 1985, and quoted forecasts for an additional 8 percent profit increase during 1986. Moreover, all seven regional companies reported higher profits in 1985.

According to CWA officials, the divestiture of AT&T has cost union members 53,000 jobs over the past 12 months. Decrying the increased contracting out of union jobs to nonunion subsidiaries and outside contractors, the union has made establishment of a training and retraining program for CWA employees at AT&T a major goal. The retraining program, Bahr said, could be designed to parallel the Ford–UAW training and development program currently in place. Ford has established a fund for the purpose of training and retraining to be used by all employees, including those facing layoff. It is funded by a 5-cent-per-hour setaside paid for by Ford. A similar program at AT&T would enable CWA members to fill job openings in other parts of the company. The union is also seeking comparable jobs within the company for employees affected by work force adjustments and plant and office closings. Bahr noted that his members will have to become more mobile as jobs and opportunities emerge in various parts of the country.

Steven M. Donahue is a labor economist at the Bureau of Labor-Management Relations and Cooperative Programs, Office of the Secretary, U.S. Department of Labor.

The convention was told that a major change in bargaining being introduced this year employs much of the same technology currently causing layoffs in the telecommunications industry. An electronic hookup using 'Easylink' satellite services will allow local unions to receive up-to-date information pertaining to AT&T district bargaining matters anywhere in the country. In addition to this daily hook-up, a nationwide conference is planned via the PBS TV network which will be beamed into closed door meetings on PBS' private downlinks. CWA's nationwide conference will allow stewards across the country to communicate face-to-face and will expedite the free exchange of necessary information on a more timely basis. The resulting rapid communication should forestall, said the Committee on the Future in its 1983 report, Regional Bell management from using whipsaw strategies and would limit internal dissent over perceived contract inequities among regions. The May 24 meeting was attended by local stewards in more than 40 cities.

Another concern of the CWA centers on health care cost containment. Bahr noted that health care costs have escalated dramatically in the past few years and that the union intends to work with AT&T to control them. The union, however, will not allow AT&T to control its costs by shifting the burden to union members and other employees, Bahr said. Such a strategy was attempted at General Telephone in early 1986 negotiations. Delegates also passed a resolution which called for the union to work for enactment of a national health care cost containment bill and to support multiunion and coalition attempts (including labor-management cooperative programs) to control costs.

In conjunction with the opening of the 1986 bargaining round, the CWA unveiled an extensive public relations compaign aimed at the Nation's decisionmakers and the general public. The program began in April with a full-page ad in a major U.S. newspaper. The cost to the national union for the overall program is expected to be approximately $1 million and does not include local participation in the program. The advertising, which will also be in broadcast form, revolves around the theme of "fair settlements from profitable companies." In addition to this ongoing campaign, there were special advertisements on Mother's Day, one of the largest phone calling days of the year. This Mother's Day campaign provided free phone calls, special local newspaper supplements, and Mother's Day cards for specified AT&T and Regional Bell employees, and revolved around the theme, "Ma Bell's gone but the CWA family lives on." Both campaigns were designed to draw positive public attention to the work of CWA members during national bargaining. The campaign arose from a recommendation of the Committee on the Future.

In public sector developments, the union noted job losses as work, formerly done by members, is contracted out by many local governments. Delegates passed a resolution which resolved to fight privatization of public sector work and to make any nonunion firm which accepts privatized work a target of union organizing drives.

Organizing. Faced with the continuing erosion of membership in an industry which has dropped from 100 percent unionization to 38 percent, organizing has become a major goal of the CWA. Delegates were notified of recent successful organizing campaigns and amalgamation agreements. In the public sector, major representation elections were won in New Jersey at Passaic County's Board of Social Services, at the University of Toledo (OH), and among environmental protection employees in western New York. The 5,800-member Union of Telegraph Employees voted to recommend a merger with the CWA, and 10,000 members of the Telephone Traffic Union in upstate New York have already merged.

In keeping with the recommendations of the Committee on the Future, CWA is targeting public sector workers as a major component of organizing campaigns. The Committee recommended that external growth be centered mainly on the information/service sectors, which is one of the fastest growing segments of the American economy. The establishment of a national vice president for public workers was the first step in this strategy. To date, the CWA is the bargaining agent for more than 80,000 public sector workers. "In addition," said Bahr, "we are establishing new lines of cooperation with the American Federation of State, County and Municipal Employees International Union and others that will lead to a cooperative effort to organize millions of unorganized government and service workers in this country."

Future organizing campaigns are being undertaken, the convention delegates were told, as part of AFL-CIO coordinated campaigns at both Northern Telecom and Blue Cross/Blue Shield. In the Blue Cross coordinated campaign, the CWA has been awarded jurisdiction in New York City and Denver. The union has already negotiated a neutrality agreement with Blue Cross of New York City under which the company agreed not to oppose CWA. The organizing campaign at the 29 plants of Northern Telecom is being coordinated by the AFL-CIO's Industrial Union Department. Northern Telecom is one of AT&T's largest U.S. telecommunications equipment competitors.

In addition, organizers for CWA have laid the groundwork for a campaign at the IBM Corp., long a bastion of nonunion work forces. While no details were given pertaining to the IBM campaign to ensure needed secrecy, delegates were told that IBM employees had been contacted. Said Bahr, "IBM Workers United has been born and has chapters around the United States. We are providing assistance and encouragement to this fledgling organization." CWA is also meeting with labor leaders around the world to extend IBM organizing to other countries.

The CWA has also targeted AT&T competitors in the telecommunications industry for organizing. Bahr stated that organizers already are actively contacting MCI employees.

Finances. Secretary–Treasurer James Booe noted in an addendum to the financial committee's report that the union was experiencing a cash flow shortage which, if not treated, would entail cutbacks or dues increases by the 1987 convention. According to the *Report of the Finance Committee,* it expects a cash shortage of approximately $3.5 million by 1987. Booe blamed the revenue shrinkage on new losses averaging an additional 1,500 dues units each month, most arising from divestiture.

Delegates to the convention rejected a proposal by the union's officers to make the convention biennial as a cost-saving measure. Citing increased expenses at a time of constricting membership, executive board officers estimated substantial annual savings if biennial conventions were to start in 1989. But delegates maintained that the union needed to continue the tradition of democracy which the CWA had built up over the years. A second amendment to hold conventions every 18 months was also rejected by convention delegates.

Elections and other activities. The completion of the CWA restructuring program reduced the number of districts from 13 to 8, resulting in the displacement of 5 incumbent district directors. The new districts were designed to parallel the Regional Bell Operating Companies' geographical structure. Elected as district vice presidents were: Jan D. Pierce, R. Ben Porch, Martin J. Hughes, Walter Maulis, Harry Ibsen, Pete Catucci, T.O. Parsons, and Vincent Maisano. In addition, M.E. Nichols and John C. Carroll were both reelected unanimously as executive vice presidents. In the national bargaining unit elections, James Irving was named AT&T communications vice president, Ronald J. Allen was elected vice president for AT&T technologies, John Browning retained his seat as vice president for communications, and Connie Bryant was elected as the first vice president for public workers. The addition of two national bargaining unit vice presidents and the transformation of two national directors into bargaining unit vice presidents arose from recommendations of the CWA's Committee on the Future, which suggested that strategy centers be created to allow the union to deal creatively and directly with external power centers (that is, AT&T).

Delegates to the convention passed a resolution supporting the AFL–CIO boycott of Royal Dutch Shell and its subsidiaries. The boycott was called because of Shell's mining and exploration activities in South Africa. In a related matter, delegates also called for complete removal of Bierne Foundation funds which are invested in South Africa. It was noted that the Foundation still had investments in two companies which do business in South Africa.

Speakers at the convention included Senator Edward Kennedy of Massachusetts, Representative James Wright of Texas, Washington, DC Mayor Marion Barry, United Farm Workers President Cesar Chavez, and AFL–CIO President Lane Kirkland. □

Postscript: CWA workers strike

A nationwide strike by 155,000 CWA members at AT&T began when the existing contract expired on May 31. However, the parties continued to negotiate on issues involving wages, job security, and changes in job classifications and pay levels.

Further information on the talks will be reported in the "Developments in Industrial Relations" section of future issues of the *Review.*

Research Summaries

Displaced workers: one year later

Richard M. Devens, Jr.

In January 1984, a special supplement to the Current Population Survey (CPS) focused on the extent of worker displacement in the labor force.[1] Using the data collected in that supplement, the Bureau of Labor Statistics defined displaced workers as those adults who, after holding a job for 3 years or more, lost or left that job because of plant shutdown or relocation, slack work, or abolishment of shift or job during January 1979 to January 1984. In several reports, BLS determined that 5.1 million persons were categorized as displaced under that definition in January 1984.[2] At the time of the survey, about three-fifths of those persons identified as displaced were employed again, about a quarter were unemployed, and the remainder were not in the labor force. About one-fourth of those displaced from a private nonagricultural job were reemployed in the same broad industrial classification as the job they had lost, while one-third returned to the same broad occupational group. Among workers who had been displaced from full-time wage and salary jobs and were reemployed in such positions, about half had weekly earnings at least as high as they had on the prior job, while more than one-fourth experienced earnings losses of 20 percent or more. What happened to these workers subsequently? Did the unemployed find jobs? Did the employed upgrade their status?

Using the longitudinal potential of the CPS, this report provides information on changes in the labor market status of displaced workers between January 1984 and January 1985. It must be noted at the outset that the use and analysis of longitudinal CPS data have technical limitations which have received much attention in the statistical community. The results of this research suggest that these types of data be treated with some circumspection and that analyses from such data be made with caution.[3] (See box.) The following sections report on the January 1985 status of workers identified in January 1984 as displaced whose CPS micro-record could be matched with a January 1985 CPS record, and on the changes in that group's labor force status.

In January 1985, workers displaced between January 1979 and January 1984 were more likely to be working and less likely to be unemployed than they had been a year earlier. Seventy-one percent of the displaced men were employed in January 1985, compared with 64 percent a year earlier and 61 percent of the women, compared with 53 percent in 1984. (See table 1.) Overall, about 30 percent of displaced workers had changed status over the year, compared with about half that change for the rest of the working-age population. Displaced workers in all labor force categories were more likely to have moved into employment and less likely to have left the labor force than comparable workers who were not displaced. (See table 2.)

A little more than half the displaced workers who were unemployed in January 1984 had jobs in 1985; among men, the remainder were more likely to still be unemployed, while women were more likely to be out of the labor force. (See table 2.) There were divergent developments in the labor market status of displaced workers of the various racial and ethnic groups. Among both blacks and whites, about 88 percent of those employed in January 1984 also were employed in 1985, while among Hispanics, that proportion was about 81 percent.[4] Hispanic workers who had been employed in 1984 were somewhat more likely to be unemployed in January 1985 than were whites or blacks. (See table 2.)

Among the unemployed of January 1984, 50 percent or more of both white and Hispanic workers were employed in

Table 1. Employment status of displaced workers by sex, race, and Hispanic origin, January 1985

[Percent distribution]

Characteristic	Total	Employed	Unemployed	Not in the labor force
Total	100.0	67.3	12.4	20.4
Men	100.0	71.0	15.2	13.8
Women	100.0	61.0	7.5	31.6
White	100.0	69.2	11.1	19.7
Black	100.0	51.2	22.0	26.7
Hispanic origin[1]	100.0	66.5	11.2	22.3

[1] Hispanics are included in both the white and black population groups.

NOTE: Data refer to persons age 20 and over with tenure of 3 years or more who lost or left a job between January 1979 and January 1984 because of plant closings or moves, slack work, or the abolishment of their positions or shifts.

Richard M. Devens, Jr. is an economist in the Division of Employment and Unemployment Analysis, Bureau of Labor Statistics.

Table 2. Labor force transition rates for displaced workers by sex, race, and Hispanic origin, January 1984 to January 1985

[Percent]

Labor force category	Displaced workers, 20 years and over[1]						Others, 20 years and over
	Total	Men	Women	White	Black	Hispanic origin[2]	
From employed to—							
Employed	87.9	88.8	85.9	87.8	89.1	80.8	89.4
Unemployed	7.8	9.2	4.6	7.7	8.4	11.5	3.0
Not in labor force	4.3	1.8	9.5	4.5	3.5	8.5	7.6
From not in labor force to—							
Employed	53.0	53.5	52.1	55.3	42.4	50.0	47.8
Unemployed	27.5	31.8	18.7	24.3	42.4	15.0	26.3
Not in labor force	19.5	14.6	28.8	20.3	15.2	35.0	25.9
From unemployed to—							
Employed	19.8	17.1	21.8	19.5	15.3	32.0	10.8
Unemployed	5.5	8.9	2.7	4.2	12.6	4.0	2.5
Not in labor force	74.6	73.7	75.5	76.3	72.1	64.0	86.7

[1] Data refer to persons age 20 and over with tenure of 3 years or more who lost or left a job between January 1979 and January 1984 because of plant closings or moves, slack work, or the abolishment of their positions or shifts.

[2] Hispanics are included in both the white and black population groups.

NOTE: The transition rate represents the proportion of workers in the first labor force category in January 1984 who were in the second labor force category in January 1985.

Table 3. Reemployed wage and salary workers by industry of lost job and industry of job held in January 1985

[Percent distribution]

Industry of job lost	Total displaced workers	Industry of job held in January 1985												Percent not employed[2]
		Mining	Construction	Manufacturing		Transportation and public utilities	Wholesale trade	Retail trade	Finance, insurance, and real estate	Services		Public administration	Farming, forestry, and fisheries

[1] Data for 1984 include nonagricultural workers in private industry.

[2] Includes displaced persons who are considered out of the labor force as well as those unemployed.

NOTE: Data refer to persons age 20 and over with tenure of 3 years or more who lost or left a job between January 1979 and January 1984 because of plant closings or moves, slack work, or the abolishment of their positions or shifts.

Table 4. Reemployed workers by occupation of lost job and occupation of job held in January 1985

[Percent distribution]

Occupation of lost job	Total displaced workers	Occupation of job held in January 1985						Percent not employed[1]
		Managerial and professional specialty	Technical, sales, and administrative support	Service occupations	Precision production, craft, and repair	Operators, fabricators, and laborers	Farming, forestry, and fishing	
Managerial and professional specialty	100.0	29.5	29.1	6.4	7.9	4.9	—	22.2
Technical, sales, and administrative support	100.0	10.6	42.5	5.1	8.0	4.0	—	29.8
Service occupations	100.0	4.8	9.6	33.5	5.9	6.4	—	39.8
Precision production, craft, and repair	100.0	5.6	6.8	6.6	30.9	18.7	.3	31.1
Operators, fabricators, and laborers	100.0	1.3	6.9	7.6	9.1	35.0	1.0	39.1
Farming, forestry, and fishing	100.0	21.2	5.8	—	9.6	26.9	7.7	28.8

[1] Includes displaced persons who are considered out of the labor force as well as those unemployed.

NOTE: Data refer to persons age 20 and over with tenure of 3 years or more who lost or left a job between January 1979 and January 1984 because of plant closings or moves, slack work, or the abolishment of their positions or shifts.

1985, compared with 4 percent of black workers. Hispanic workers were far more likely than white or black to have moved from unemployed to not in the labor force.

Displaced workers not in the labor force in January 1984 tended to remain in that category, in large part because they were concentrated in the older age groups. Overall, about three-quarters of those not in the labor force in January 1984 were also out of the labor force a year later. This tendency was most pronounced among whites and least among persons of Hispanic origin. Hispanics were the most likely of the three major racial and ethnic groups to have moved from not in the labor force to employed, and black workers were the most likely to have moved from out of the labor force to unemployed.

A useful indicator of the degree to which displaced workers are reintegrated in the labor force is the proportion who return to the same industry or occupation.[5] In January 1985, the proportion of displaced workers who were reemployed in a private nonagricultural industrial group broadly similar to that of the job they lost was 28 percent. In January 1984, the corresponding proportion was 23 percent. The industries with the highest rate of rehiring were professional services (40 percent) and retail trade (36 percent); the lowest rate was in finance, insurance, and real estate, in which many workers, displaced from the industry, had found jobs in the services field. (See table 3.)

Among occupational groups, workers in technical, sales, and administrative support occupations were most likely to be reemployed in a broadly similar occupation; farming, forestry, and fishing workers were least likely. In all, by January 1985, 34.5 percent of displaced workers were reemployed in the same broad occupational group as they worked in at the job they lost. (See table 4.) This proportion is a slight change from that of a year earlier.

Limitations of the data base

The 59,500 households that are interviewed in the monthly Current Population Survey (CPS) comprise eight national subsamples or rotation groups. One new group is introduced each month, is interviewed for 4 consecutive months, is out of the sample for 8 months, and is returned for 4 more months of interviews. Thus, in any 2 consecutive months, 75 percent of the addresses are common to each month, and, in months a year apart, January to January, for instance, 50 percent of the addresses are common. This sample rotation scheme gives the CPS its longitudinal flavor.

In all phases of administration of the CPS—sampling, interviewing, data preparation and processing—there are factors that affect the survey's usefulness as a longitudinal data base. For example, because the interviewer goes to a sample address, not to a household or specific persons living at an address, those who move into, or out of, a sample address between interviews cannot be matched. Other sources of difficulty include respondent bias (answering identical questions differently when there is no change in status), interviewer error, transcription mistakes, processing problems, and noninterviews.

The CPS is designed to provide accurate estimates of labor market activity in a particular month. Longitudinal aspects of the survey are a byproduct and, as such, are subject to defects and limitations that must be fully considered in any application of the data.

—Adapted from Ronald Dopkowski, "Practical Limitations on Using the CPS as a Longitudinal Survey," *Using the Current Population Survey as a Longitudinal Data Base*, Report 608 (Bureau of Labor Statistics, 1980), pp. 3–4.

Table 5. Current earnings relative to previous earnings of displaced workers reemployed in full-time wage and salary jobs by industry of lost job, January 1985

[Percent distribution]

Industry of lost job	Earnings in January 1985 relative to those of lost job				
	Total	20 percent or more below	Below, but within 20 percent	Equal or above, but within 20 percent	20 percent or more above
Total[1]	100.0	17.9	15.6	24.5	34.9
Construction	100.0	—	11.1	33.3	55.6
Manufacturing	100.0	23.0	17.9	22.6	30.9
Durable goods	100.0	24.9	21.5	18.6	29.3
Nondurable goods	100.0	19.9	11.7	30.0	33.6
Transportation and public utilities	100.0	—	25.7	47.3	20.3
Wholesale and retail trade	100.0	10.5	—	38.9	40.7
Finance and service industries	100.0	—	17.3	15.4	67.3
Public administration	100.0	52.8	—	—	44.4

[1] Includes mining, not shown separately.

NOTE: Data refer to persons age 20 and over with tenure of 3 years or more who lost or left a job between January 1979 and January 1984 because of plant closings or moves, slack work, or the abolishment of their positions or shifts. Includes workers who did not report earnings on lost job.

Another useful comparison to make in assessing the labor market experience of reemployed workers is to examine current earnings relative to previous earnings.[6] To minimize the effect of differences in hours worked on weekly earnings, the earnings data were compared only for persons who lost a full-time wage and salary position and were similarly reemployed. Among such workers, almost 60 percent earned as much or more in the January 1985 job as they had in the lost job. However, about 18 percent earned substantially less—20 percent or more—in their new job than they had earned in their previous employment. (See table 5.) In January 1984, only about half of the reemployed full-time wage earners made as much, or more, than they had in their old jobs and more than a quarter had suffered losses of 20 percent or more.

Overall, persons displaced during the 1979–83 period appeared to be generally better off in January 1985 than they had been in January 1984. Individuals were more likely to be working and, when employed in full-time jobs, were more likely to have matched their former earnings. A sizable group, however, continued to have difficulty in the labor market. For the most part, those with continuing difficulty were blacks, blue-collar workers, and persons formerly employed in manufacturing. More information on displaced workers will be available by the end of the 1986, when information from a second survey of displaced workers becomes available.[7] □

——FOOTNOTES——

[1] The displaced worker supplement was administered to all adult (20 years and older) respondents to the January 1984 Current Population Survey which is conducted by the Bureau of the Census for the Bureau of Labor Statistics. Those who answered in the affirmative to the question, "In the past 5 years, that is, since January 1979, has (name of respondent) lost or left a job because of a plant closing, an employer going out of business, a layoff from which (name of respondent) was not recalled, or other similar reasons?", were asked a series of more detailed questions about that job loss.

[6] *Ibid*.

[7] In January 1986, a second displaced workers supplement to the Current Population Survey was administered by the Census Bureau, sponsored jointly by the Employment and Training Administration and the Bureau of Labor Statistics. The data from the survey cover displacements over the January 1981–86 period.

Occupational pay structure in petroleum refineries

Hourly earnings of production workers in the Nation's petroleum refineries averaged $14.20 in June 1985, according to a Bureau of Labor Statistics wage survey.[1] Just over nine-tenths of the 51,203 workers covered by the survey earned between $12 and $16 an hour; about one-half had earnings within a $1 range—$14.50 to $15.50. The number of refineries paying single rates for individual occupations contributed substantially to this narrow spread, as did the relatively large proportion of skilled workers in the industry, the concentrations of employment in relatively few large companies, and the high degree of collective bargaining with a single union (the Oil, Chemical and Atomic Workers International Union, AFL–CIO).

Refinery workers averaged 23 percent more in June 1985 than in May 1981, when the last survey was conducted.[2] This increase compares with a 22-percent rise in the wage and salary component of the Bureau's Employment Cost Index for all manufacturing industries between the second quarters of 1981 and 1985. The petroleum industry's wage change largely reflected increases granted to nearly seven-eighths of the workers under collective bargaining agreements. Provisions for automatic cost-of-living adjustments (COLA), triggered primarily by specified changes in the BLS Consumer Price Index, applied to less than 5 percent of the work force.

Among the eight geographic regions studied in 1985, pay levels for six fell within 4 percent of the industry's nationwide average ($14.20 an hour). Averages were about 10 percent below this mark in the Western Pennsylvania-West Virginia region and in the Texas Inland-North Louisiana-Arkansas region. Regionally, pay levels of production and related workers ranged from $12.65 in Western Pennsylvania-West Virginia to $14.62 in the East Coast region. Workers in the Texas-Louisiana-Gulf Coast region, where two-fifths of the industry's work force was concentrated, averaged $14.50 an hour.

Twenty-six occupations, accounting for nearly four-fifths of the production workers, were selected to represent the wage structure and activities of production and related workers in the industry. (See table 1.) Among these jobs, average hourly earnings ranged from $11.41 for laborers to $15.38 for chief operators of stills. Assistant operators, who help chief operators maintain stills, accounted for one-fifth of the industry's work force and averaged $14.45 an hour. Chief operators' helpers, who maintain required temperatures in furnaces of stills and pumpers, averaged $13.65 and $14.49 an hour, respectively.

Average hourly earnings of the nine journeyman maintenance trades studied were closely grouped—ranging from $14.07 for machinery mechanics to $14.82 for boilermakers. General mechanics, the most numerous of these workers, averaged $14.60 an hour. General mechanic includes skilled workers operating under maintenance craft consolidation plans (which combine two crafts or more into a single job), and mechanics working in small refineries where specialization in maintenance work is impractical. Maintenance trades helpers averaged $12.77—9 percent below the lowest paid journeyman trade studied.

Paid holidays, usually 10 days annually, were provided to all production workers in the industry. All refineries studied also provided paid vacations to their production workers after qualifying periods of service. Typically, workers received 2 weeks of vacation pay after 1 year of service, 3 weeks after 5 years, 4 weeks after 10 years, 5 weeks after 15 years, and 6 weeks after 30 years. Virtually all refinery workers were provided at least part of the cost of life, hospitalization, surgical, basic medical, and major medical insurance, as well as retirement plans. Dental insurance and full or partial paid sick leave were provided to just over nine-tenths of the workers. Accidental death and dismemberment insurance was available to slightly more than four-

Table 1. Average straight-time hourly earnings and number of production and related workers in selected occupations, petroleum refineries, United States, June 1985

Occupation	Number of workers	Average (mean) hourly earnings[1]
Maintenance:		
Boilermakers	756	$14.82
Carpenters	370	14.63
Electricians	1,316	14.69
Helpers, maintenance trades	717	12.77
Instrument repairers	1,490	14.74
Machinists	1,905	14.74
Mechanics, general	4,848	14.60
Mechanics (machinery)	534	14.07

[1] Wage data are straight-time earnings which exclude premium pay for overtime and for work on weekends, holidays, and late shifts. Cost-of-living pay increases (but not bonuses) were included as part of the workers' regular pay. Excluded were performance bonuses and lump-sum payments of the type negotiated in the auto and aerospace industries as well as profit-sharing payments, attendance bonuses, Christmas or yearend bonuses, and other nonproduction bonuses.

[2] Includes data for subcategories not shown separately.

fifths of the work force; long-term disability insurance, to nearly three-fifths; and sickness and accident insurance, to two-fifths. Health plan coverage was usually financed jointly by the employer and employee.

The petroleum refining industry includes establishments engaged primarily in producing gasoline, kerosene, distillate fuel oil, residual fuel oils, lubricants, and other products from crude petroleum and its fractionation products. Production is accomplished through straight distillation of crude oil, redistillation of unfinished petroleum derivatives, cracking, or other processes as defined in the *Standard Industrial Classification Manual, 1972,* prepared by the U.S. Office of Management and Budget.

The 142 refineries within scope of the survey (those with at least 100 workers) employed 51,203 production and related workers in June 1985, down 22 percent from the 65,566 recorded in May 1981. Employment declines among the eight regions studied ranged from 2 percent in the West Coast to 40 percent in the East Coast, but typically ranged from about 20 to 30 percent among the other six regions. Much of this employment loss resulted from a lesser demand for petroleum products and the increased use of computerized processing equipment and other technological innovations.

Gasoline—including naphtha—was the major product of refineries employing more than nine-tenths of the production workers covered by the survey. Other products included distillated fuel oil, residual fuel oil, jet fuel, lubricating oil, and asphalt. Most workers in the Western Pennsylvania-West Virginia region were employed in refineries that were primarily manufacturing products other than gasoline, usually lubricating oil or distillate fuel oil. Refineries employing nearly three-fifths of the industry's workers were also processing petrochemicals.

A comprehensive report on the survey findings of *Industry Wage Survey: Petroleum Refining, June 1985* (Bulletin 2255), may be purchased from the Superintendent of Documents, Washington, DC 20402, or from the Bureau of Labor Statistics, Publications Sales Center, P.O. Box 2145, Chicago, IL 60690. ☐

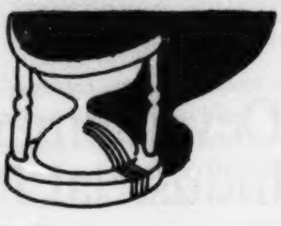
Major Agreements Expiring Next Month



This list of selected collective bargaining agreements expiring in August is based on information collected by the Bureau's Office of Wages and Industrial Relations. The list includes agreements covering 1,000 workers or more. Private industry is arranged in order of Standard Industrial Classification.

Industry or activity	Employer and location	Labor organization[1]	Number of workers
Private			
Construction	National Electrical Contractors Association, Inc., Southeast Texas Chapter, Houston Division (Texas)	Electrical Workers	3,700
	Roofing Contractors Association of Southern California, Inc., and others (California)	Roofers	1,000
Apparel	National Neckwear Conference (New York, NY)	Clothing and Textile Workers	1,600
Chemicals	Avtex Fibers Inc. (Interstate)	Clothing and Textile Workers	1,500
Leather	Massachusetts Leather Manufacturers Association (Massachusetts)	Leather Workers	1,000
Stone, clay, and glass products	Wheaton Industries (Millville, NJ)	Glass, Pottery, Plastics	1,500
Primary metals	Armco Steel Corp. (Interstate)	Steelworkers	14,000
	Jones & Laughlin Steel Corp. (Interstate)	Steelworkers	32,000
	Republic Steel Corp. (Interstate)	Steelworkers	30,000
	Sharon Steel Corp. (Interstate)	Steelworkers	2,850
	Bethlehem Steel Co. (Interstate)	Steelworkers	49,000
	United States Steel Corp. (Interstate)	Steelworkers	102,000
	Babcock & Wilcox Co., Tubular Products Division (Beaver Falls, PA)	Steelworkers	4,500
	National Steel Corp. (Interstate)	Steelworkers	15,000
	Inland Steel Co. (Interstate)	Steelworkers	21,100
	Northwestern Steel and Wire Co. (Sterling, IL)	Steelworkers	1,600
Fabricated metal products	Fisher Controls Co. (Marshalltown, IA)	Auto Workers	1,300
Machinery	Cameron Iron Works, Inc. (Houston, TX)	Machinists	1,700
	Timken Co. (Canton, OH)	Steelworkers	8,000
Communication	Regional telephone companies: Ameritech, Bell Atlantic, Bell South, Nynex, Pacific Telesis, Southwestern Bell, and U.S. West	Communications Workers; Electrical Workers (IBEW); and others	375,000
Utilities	Alabama Power Co. (Alabama)	Electrical Workers (IBEW)	3,950
	Wisconsin Electric Power Co. (Wisconsin)	Electrical Workers (IBEW)	2,050
Restaurants	East Bay Restaurant Association (Alameda, CA)	Hotel Employees and Restaurant Employees	2,300
	Hotel Employers Association of San Francisco (California)	Hotel Employees and Restaurant Employees	5,000
Public			
Education	Florida: Broward County teachers	Teachers	7,700
	Brevard County Board of Education, teachers	Teachers	2,900
	Illinois: University of Illinois (Chicago), clerical	Service Employees	1,300
	Peoria Board of Education, teachers	Teachers	1,050
	Indiana: Fort Wayne Board of Education, teachers	Education Association (Ind.)	1,500
	Kansas: Kansas City teachers	Education Association (Ind.)	1,500
	Michigan: Warren Consolidated School District, teachers	Education Association (Ind.)	1,100
	New Mexico: Albuquerque Board of Education, teachers	Teachers	4,800
	Ohio: Columbus Board of Education, teachers	Education Association (Ind.)	4,500
	Pennsylvania: Philadelphia Board of Education, blue collar	Firemen and Oilers	5,000
General government	Ohio: Cincinnati general unit	Service Employees	2,800

Developments in Industrial Relations

High court backs laid-off white teachers

The Supreme Court rejected an affirmative action plan that permitted black teachers in Jackson, MI, to retain their jobs while more senior white teachers were laid off. The plan had been instituted by the Jackson school board and the teachers' union after they had determined that the percentage of black teachers in the school system was substantially less than the percentage of black students. Despite the Court's ruling, it appears that the validity of using employment goals and quotas to equalize employment opportunities must await clarification in two cases scheduled to be heard by the Court this term. This is apparent from the fact that the Court was sharply divided in the Jackson case: there were three opinions by the five-member majority and two by the minority.

Not surprisingly, both proponents and opponents of the use of goal and quota systems claimed that the decision strengthened or at least did not nullify their positions. Terry Eastland, spokesman for the Department of Justice, said the decision "leaves for another case the bottom-line gut issue of when race may be taken into account in employment." During the arguments before the Court, Assistant Attorney General William Bradford Reynolds had expressed the Reagan Administration's position that affirmative action plans may not use quotas or goals and that the Government should intervene only on behalf of individuals who can prove that they are victims of specific acts of discrimination, rather than on behalf of groups or classes of people seeking redress of alleged broad patterns of discrimination.

The events leading to the decision began in 1973, when the school board and the Jackson Education Association revised the seniority provisions in their contract by providing that "at no time will there be a greater percentage of minority personnel laid off than the current percentage of minority personnel at the time of layoff." This change was based on a finding that in 1969, 15.2 percent of the students but only 3.9 percent of the teachers were black. When Jackson was forced to lay off teachers in 1981 and 1982, the contract requirement was followed and some black teachers were retained while several white teachers with more service were terminated. Eight of the laid-off white teachers then sued the school board, contending that the action violated their rights to equal protection under the Fourteenth Amendment to the Constitution. A Federal district judge ruled in favor of the school district, and his decision was upheld by the U.S. Court of Appeals for the Sixth Circuit.

In reversing the Court of Appeals' decision, the Supreme Court said that the board of education did, in fact, violate the equal protection clause of the Fourteenth Amendment. Writing for four members of the Court, Justice Lewis Powell rejected the Court of Appeals' position that the school board's efforts to provide "role models" for minority students or its efforts to reduce the effects of broad "societal discrimination" justified race-based layoffs. Justice Powell said, "This Court has never held that societal discrimination alone is enough to justify a racial classification. Rather, the Court has insisted upon some showing of prior discrimination by the governmental unit involved before allowing limited use of racial classifications to remedy such discrimination." In this case, Justice Powell said, there was no evidence that the school board had determined that prior discrimination in hiring teachers had actually occurred. In another aspect of the ruling, Justice Powell said the Court's 1977 ruling in *Hazelwood School District* vs. *United States* established that the proper statistical measure the school board should have used in assessing the makeup of the system's staff of teachers was the percentage of black teachers relative to the pool of available teachers, rather than relative to the racial composition of the student body.

In a concurring opinion, Justice Sandra Day O'Connor said that the petitioner had proved that the"layoff provision is 'not narrowly' tailored to achieve its asserted remedial purpose by demonstrating that the provision is keyed to a hiring goal that itself has no relation to the remedying of employment discrimination."

In another concurring opinion, Justice Byron White said the board's action clearly violated the equal protection clause of the Fourteenth Amendment, adding, "Whatever the legitimacy of hiring goals or quotas may be, the discharge of white teachers to make room for blacks, none of whom has been shown to be a victim of any racial discrimination, is quite a different matter. I cannot believe that in order to integrate a work force, it would be permissible to discharge whites and hire blacks until the latter comprised a suitable percentage of the work force."

In a dissenting opinion, Justice Thurgood Marshall, joined by Justices William Brennan and Harry Blackmun, said the Fourteenth Amendment does not prohibit "a union

---

"Developments in Industrial Relations" is prepared by George Ruben of the Division of Developments in Labor-Management Relations, Bureau of Labor Statistics, and is largely based on information from secondary sources.

and a local school board from negotiating a collective bargaining agreement that apportions layoffs between two racially determined groups as a means of preserving the effects of an affirmative hiring policy, the constitutionality of which is unchallenged." Justice Marshall accused the Court majority of overlooking the racial tensions and threats of litigation that prevailed when the job retention preference was adopted and concluded, "a public employer, with the full agreement of its employees, should be permitted to preserve the benefits of a legitimate affirmative-action hiring plan even while reducing its work force."

In a separate dissent, Justice John Paul Stevens said the board's efforts to attain "multi-ethnic representation" on the faculty were permissible under the Fourteenth Amendment.

Eastern Airlines update

The travails of Eastern Airlines continue, but there was some hope for improvement in the financial condition of the carrier when the U.S. Department of Justice dropped its objections to Texas Air Corp.'s acquisition of Eastern (approval is still required from the Department of Transportation). In another unsettled matter, Eastern was continuing a court case to force the Machinists union to reopen its contract and negotiate wage and benefit reductions and changes in work rules similar to those negotiated by the Air Line Pilots and Transport Workers unions.

The latest series of crises at Eastern began in late 1985, when company chairman Frank Borman and president Joseph Leonard notified employees that, "the temporary [wage concession] programs that we have participated in since 1983 simply will not permit us to prosper in the new economic environment of our industry. . . . We must design and implement a restructuring of our employment costs that will allow us to resume the success of early 1985." During the first half of 1985, Eastern—which had not showed an annual profit since 1979—earned $46.4 million, but prospects for a full-year profit were dimmed by intensifying fare wars. (In fact, Eastern did show a profit of $6.3 million for the year.)

Following this announcement, Eastern informed the unions that its survival required a permanent pay cut of 22 percent; two-tier pay systems; changes in work rules, including more monthly flying time by plane crews; and some reduction in benefits. The proposed 22-percent pay cut would be only a few percentage points more than the temporary cuts the unions had negotiated in 1983. The temporary cuts—to apply only during 1984—were 20 percent for the 4,000 pilots represented by the Air Line Pilots Association; and 18 percent for the 6,800 flight attendants represented by the Transport Workers and for the 13,000 mechanics and related ground service employees represented by the Machinists union. In 1985, the Air Line Pilots and the Machinists had negotiated agreements with the carrier to restore the temporary cuts in January 1986. The Machinists contract, extending through 1987, also provided for pay increases in 1986 and 1987. The Transport Workers did not settle at the same time as the other unions, contending that Eastern refused to offer the same terms as those accepted by the other unions, and that Eastern's extension of the pay reduction into 1985 violated the 1983 agreement.

At yearend, the pressure on Eastern and the unions increased when the company's lenders set a March 31 deadline for negotiation and ratification of cost-reducing labor contracts. If the parties were unable to agree, the lenders could have seized Eastern's assets because the company would have been in default on it $2.5 billion in debts.

In mid-January, Eastern announced it was cutting 1,010 flight attendants from the payroll and was reducing the pay of the remaining attendants by 20 percent and increasing their flight hours to about 63 per month (from 52). Finally, the company said that it would institute a two-tier pay system. Eastern's action came after the expiration of a 30-day "cooling off" period declared by the National Mediation Board under the Railway Labor Act. The end of the 30-day period freed the union to strike and the company to impose contract changes or to lock out employees.

In late February, Frank Lorenzo, Chairman of Texas Air Corp., offered to buy Eastern. This impelled the unions to intensify efforts to settle on cost reductions and thus end the carrier's need for assistance from Lorenzo, who is viewed with disfavor by the unions because of his 1983 acquisition of Continental Airlines and subsequent dismissal of the union-represented employees, followed by resumption of operation at reduced pay levels. The Air Line Pilots settled as Eastern's board of directors was meeting to consider Lorenzo's offer. The Transport Workers claimed that it also settled at that time, but Eastern said that the document was never properly completed. Eastern rejected the Machinists' offer of a 15-percent pay cut because the union made it contingent on the resignation of company chairman Frank Borman. (Later, the airline initiated a lawsuit against the Machinists in an effort to force the union to negotiate on cost reduction measures, contending that the offer to cut pay in exchange for the resignation of Borman was a valid reopening of the contract.)

The 28-month Air Line Pilots accord calls for a 20-percent permanent pay cut that could be offset by a possible 1988 distribution to employees from an allocation equal to 5 percent of any 1987 profits. Other terms included increased flying hours; a two-tier pay system under which new employees receive 20 percent lower pay during their first 5 years on the job; a cut in vacation time; and a requirement that workers begin paying part of their medical insurance premiums.

The Transport Workers also negotiated a 33-month contract containing similar terms. It also provides for binding arbitration of several issues which arose during the workers balloting and threatened the entire accord.

In conjunction with the Transport Workers settlement, Eastern also agreed to recall the laid-off flight attendants and to pay employees part of the money they lost because the company extended the pay cut through 1985. The payment was calculated at 6 percent of earnings from February 1, 1985, through January 20, 1986.

Flight attendants at TWA end strike

At TWA, the Independent Federation of Flight Attendants ended its 2½-month strike but rejected the carrier's last offer. Return-to-work prospects were uncertain for the 6,000 employees. Apparently, the union decided to end the stoppage because TWA was hiring replacements—and some strikers had returned to work—permitting the airline to attain nearly full operation. Just before the employees voted to accept the offer, TWA announced that all but 600 of their jobs had been filled.

In May 1985, financier Carl Icahn began a drive to gain control of the financially stricken TWA. In August, the Air Line Pilots and the Machinists agreed to cuts in compensation and changes in work rules to aid Icahn in gaining control. To some extent, the unions were impelled to cooperate because they feared that Frank Lorenzo of Texas Air Corp. might outbid Icahn for control of the airlines.

At yearend, Icahn was encountering difficulties in gaining the financial backing necessary to complete the acquisition, leading the unions to agree to modifications of the original accords. Reportedly, the combined cut in compensation resulting from the settlements amounted to 23 percent for employees represented by the Air Line Pilots and 17 percent for those represented by the Machinists.

The Flight Attendants did not settle with TWA in 1985. Instead, it continued bargaining into 1986. Talks became increasingly difficult, with the union contending that TWA was seeking larger cuts in compensation than those accepted by the other unions. Finally, the union struck in March, but as time passed, the stoppage became less and less effective, leading to the union members' decision to end the strike.

Illinois State workers; firefighters accords

About 40,000 employees of the State of Illinois were covered by a 3-year contract negotiated by the State, County and Municipal Employees. The agreement, effective July 1, provides for general wage increases of 4 percent on October 1, 1986, 4.5 percent on July 1, 1987, and 5 percent on July 1, 1988. Employees at the top of their rate range—about half of those in the unit—received an additional 2-percent increase on July 1, 1986. The State also agreed to provide $4 million for special pay increases to employees the parties agree are underpaid.

The accord, which covered workers in a variety of State agencies, also provides for negotiations on the impact on employees of the closing of any facilities; a new State-financed dental plan; and reduced deductibles and copayments for workers who use preferred provider medical care organizations.

Also in Illinois, 4,500 Chicago firefighters were covered by a 3-year arbitration award. Martin O. Holland, President of Local 2 of the International Association of Fire Fighters, said the award "was worth the wait," while Carl S. Tomnberg, the city's counsel for the negotiations, said the award gives back "operational control of the fire department to the city." The parties' contract expired on December 31, 1983, and the arbitration period was concluded in March 1986, when arbitrator Irwin M. Lieberman issued his findings.

The union won its demand for five person staffing of fire companies, but the city won the right to 15 staffing variances per day, meaning that 15 companies can be comprised of four firefighters.

Other terms included, a reduction in the workweek to an average of 44.8 hours, from 46.7; 12 paid furlough days (formerly 10); 13 paid holidays (formerly 12); $15,000 city-financed life insurance (formerly $5,000); and elimination of the annual clothing allowance, with the city now required to open a commissary to provide uniforms and work clothes and to give each employee $50 a year for maintenance.

The settlement was financed by a $45.4 million a year increase in property taxes voted by the city council, which also appropriated $500,000 to aid employees who retired or became disabled during the arbitration period or to aid the survivors of firefighters who died.

Oscar Mayer plant shutdown averted

A shutdown of Oscar Mayer Food Corp.'s hog slaughtering plant in Perry, IA, was averted when employees approved a new 3-year contract. Included was a company guarantee that it will not shut down the facility for 18 months and will give a 90-day notice of any intention to shut down. The workers had turned down an earlier offer because it did not include these provisions.

The accord also raised the base pay rate to $9 an hour, from $8.69, effective immediately, and to $9.10 in April 1987. According to a company official, the new rates will be among the highest in the slaughtering industry.

UAW ends strike at Champion Spark Plugs

In the automobile parts industry, Champion Spark Plug Co. and the Auto Workers settled, ending a 10-week strike. The settlement covered 2,400 active and 600 laid-off workers at two plants in Ohio and one each in Michigan, Iowa, and Ontario, Canada.

The workers will receive $500 lump-sum payments in the first and second years and a 2.25-percent wage increase in the final year. The cost-of-living clause was continued, but 3 cents an hour will be diverted from each resulting quarterly pay adjustment.

The contract, running to February 1, 1989, also provided for benefit changes: adoption of health care cost containment requirements such as precertification for hospital admissions and second opinions on surgery; increased life insurance for retirees; a pension rate of $22.50 a month (was $18.95) for each year of credited service, a $1,205 a month pension (was $935) for employees retiring under the 30-year-and-out provision, and two payments of up to $200 each for current retirees.

UAW settle at former Bendix plants

The Auto Workers and Allied Corp. settled for 4,800 workers at former Bendix Corp. plants that were acquired by Allied in 1983. The plants, located in Michigan, Indiana, New Jersey, New York, and California, produce parts for the automobile, truck, aerospace, and shipbuilding industries.

The 3-year contract, scheduled to expire on May 3, 1989, does not provide for specified wage increases but the employees will receive $700 lump-sum payments in May of each year. The cost-of-living provision was continued, subject to a 2-cent-an-hour diversion from each of the first eight possible quarterly adjustments. There will be no diversion from the last three possible adjustments, which will be accrued and paid in lump sums at the end of the 3-month periods, rather than being paid immediately in regular weekly pay checks.

In other changes, the pension rate was increased to $20.50 a month for each year of credited service (from $18.45), and the 30-and-out pension was increased to $1,100 a month (from $935). □

'Solidarity' ends at the border

It seems very clear that employee interest in multinational union action is probably close to being nonexistent. The idea that workers of one country will enthusiastically, or even reluctantly, support the cause of their brothers and sisters in another country simply lacks credible evidence. Typical is the case of rubber workers. Members of the same union in the United States and Canada supplied each other's markets in the Canadian strike of 1974 and the U.S. strike 2 years later. In the latter stoppage, the companies sent molds to European plants for manufacture there and imported tires from these plants to the United States without any interference, despite calls for boycotts by American and multinational union organizations. This is typical of most such situations. Claims of international solidarity actions during such strikes rarely amount to more than leaflets promising support, statements of "solidarity" by union officials, or letters from foreign unions to company headquarters' officials "demanding" that they agree to the striking union's terms.

Book Reviews

A familiar cure

The Economics of Unemployment: A Comparative Analysis of Britain and the United States. By James J. Hughes and Richard Perlman. New York, Cambridge University Press, 1984. 258 pp.

The main theme of this book is that unemployment is mainly a consequence of inadequate demand, the only cure therefore being stimulation of aggregate demand. Through this work, James J. Hughes and Richard Perlman attempt to spark renewed interest in the subject, which they feel has been given short shrift in the two countries studied.

The reader is asked to accept at face value the premise that demand is indeed inadequate. Many, however, will find that a difficult idea to accept. In the United States, for example, we have the following phenomena: consumer debt per capita continues to break records; ditto government spending; the dollar is too strong for its own good, as spending on foreign goods skyrockets. In addition, the economy has performed remarkably well in employing the legions of baby-boomers, and their spouses. Indeed, the proportion of the population which is in the labor force has continually been increasing. If demand needs to be expanded, just where will it come from? Unfortunately, this question is not addressed by the authors.

It should by now surprise no one that the authors are of the Keynesian persuasion, a gutsy proposition these days. They feel that ". . . there needs to be a renewed attempt to develop a spirit of international Keynesianism . . ." And they come to bat for the beleaguered Phillips curve.

The authors of *The Economics of Unemployment* provide an excellent consolidation of recent research, presented in their theoretical frameworks. Opposing viewpoints are aired. There are separate chapters on unemployment statistics, unemployment categories, macroeconomic issues, relationship with inflation, effect of minimum wage legislation, unemployment insurance, experience since World War II, high-incidence population groups, costs, and the authors' prescription. The book suffers from a paucity of punctuation, which makes the going rough in some places. Also evident is the authors' penchant for the use of both tautology and understatement.

The reader will find *The Economics of Unemployment* heavier with polemic and politics than the title would indicate. The current U.S. and UK administrations are accused of ". . . creating unemployment to dampen down wage inflation . . . ," for example. To a large extent, the book is a call for the revival of Keynesianism, which leads one to question the objectivity of the analysis.

The book concludes by advocating an expanded scope for the Federal Government. The authors' program features expansionary demand policies, together with a flexible incomes policy and an active manpower policy. No evidence or argument is presented to support central government's increased role in economic decisionmaking. Apparently, the authors assume that the reader shares their distrust of free markets.

NOTES ON CURRENT LABOR STATISTICS

This section of the *Review* presents the principal statistical series collected and calculated by the Bureau of Labor Statistics: series on labor force, employment, unemployment, collective bargaining settlements, consumer, producer, and international prices, productivity, international comparisons, and injury and illness statistics. In the notes that follow, the data in each group of tables is briefly described, key definitions are given, notes on the data are set forth, and sources of additional information are cited.

General notes

The following notes apply to several tables in this section:

Seasonal adjustment. Certain monthly and quarterly data are adjusted to eliminate the effect on the data of such factors as climatic conditions, industry production schedules, opening and closing of schools, holiday buying periods, and vacation practices, which might prevent short-term evaluation of the statistical series. Tables containing data that have been adjusted are identified as "seasonally adjusted." (All other data are not seasonally adjusted.) Seasonal effects are estimated on the basis of past experience. When new seasonal factors are computed each year, revisions may affect seasonally adjusted data for several preceding years. (Seasonally adjusted data appear in tables 1–3, 4–10, 13, 14, 17 and 18.) Beginning in January 1980, the BLS introduced two major modifications in the seasonal adjustment methodology for labor force data. First, the data are seasonally adjusted with a procedure called X–11 ARIMA, which was developed at Statistics Canada as an extension of the standard X-11 method previously used by BLS. A detailed description of the procedure appears in *The X–11 ARIMA Seasonal Adjustment Method* by Estela Bee Dagum (Statistics Canada, Catalogue No. 12–564E, February 1980). The second change is that seasonal factors are calculated for use during the first 6 months of the year, rather than for the entire year, and then are calculated at mid-year for the July-December period. However, revisions of historical data continue to be made only at the end of each calendar year.

Seasonally adjusted labor force data in tables 1 and 4–10 were revised in the February 1986 issue of the *Review*, to reflect experience through 1985.

Annual revisions of the seasonally adjusted payroll data shown in tables 13, 14, and 18 were made in the July 1986 *Review* using the X-11 ARIMA seasonal adjustment methodology. New seasonal factors for productivity data in table 42 are usually introduced in the September issue. Seasonally adjusted indexes and percent changes from month to month and from quarter to quarter are published for numerous Consumer and Producer Price Index series. However, seasonally adjusted indexes are not published for the U.S. average All Items CPI. Only seasonally adjusted percent changes are available for this series.

Adjustments for price changes. Some data—such as the Hourly Earnings Index in table 17—are adjusted to eliminate the effect of changes in price. These adjustments are made by dividing current dollar values by the Consumer Price Index or the appropriate component of the index, then multiplying by 100. For example, given a current hourly wage rate of \$3 and a current price index number of 150, where 1967 = 100, the hourly rate expressed in 1967 dollars is \$2 (\$3/150 × 100 = \$2). The \$2 (or any other resulting values) are described as "real," "constant," or "1967" dollars.

Additional information

Data that supplement the tables in this section are published by the Bureau in a variety of sources. News releases provide the latest statistical information published by the Bureau; the major recurring releases are published according to the schedule preceding these general notes. More information about labor force, employment, and unemployment data and the household and establishment surveys underlying the data are available in *Employment and Earnings*, a monthly publication of the Bureau. More data from the household survey is published in the two-volume data book—*Labor Force Statistics Derived From the Current Population Survey*, Bulletin 2096. More data from the establishment survey appears in two data books—*Employment, Hours, and Earnings, United States*, and *Employment, Hours, and Earnings, States and Areas*, and the annual supplements to these data books. More detailed information on employee compensation and collective bargaining settlements is published in the monthly periodical, *Current Wage Developments*. More detailed data on consumer and producer prices are published in the monthly periodicals, *The CPI Detailed Report*, and *Producer Prices and Price Indexes*. Detailed data on all of the series in this section are provided in the *Handbook of Labor Statistics*, which is published biennally by the Bureau. BLS bulletins are issued covering productivity, injury and illness, and other data in this section. Finally, the *Monthly Labor Review* carries analytical articles on annual and longer term developments in labor force, employment and unemployment; employee compensation and collective bargaining; prices; productivity; international comparisons; and injury and illness data.

Symbols

p = preliminary. To increase the timeliness of some series, preliminary figures are issued based on representative but incomplete returns.

r = revised. Generally, this revision reflects the availability of later data but may also reflect other adjustments.

n.e.c. = not elsewhere classified.

n.e.s. = not elsewhere specified.

COMPARATIVE INDICATORS
(Tables 1–3)

Comparative indicators tables provide an overview and comparison of major BLS statistical series. Consequently, although many of the included series are available monthly, all measures in these comparative tables are presented quarterly and annually.

Labor market indicators include employment measures from two major surveys and information on rates of change in compensation provided by the Employment Cost Index (ECI) program. The labor force participation rate, the employment-to-population ratio, and unemployment rates for major demographic groups based on the Current Population ("household") Survey are presented, while measures of employment and average weekly hours by major industry sector are given using nonagricultural payroll data. The Employment Cost Index (compensation), by major sector and by bargaining status, is chosen from a variety of BLS compensation and wage measures because it provides a comprehensive measure of employer costs for hiring labor, not just outlays for wages, and it is not affected by employment shifts among occupations and industries.

Data on **changes in compensation, prices, and productivity** are presented in table 2. Measures of rates of change of compensation and wages from the Employment Cost Index program are provided for all civilian

nonfarm workers (excluding Federal and household workers) and for all private nonfarm workers. Measures of changes in: consumer prices for all urban consumers; producer prices by stage of processing; and the overall export and import price indexes are given. Measures of productivity (output per hour of all persons) are provided for major sectors.

Alternative measures of wage and compensation rates of change, which reflect the overall trend in labor costs, are summarized in table 3. Differences in concepts and scope, related to the specific purposes of the series, contribute to the variation in changes among the individual measures.

Notes on the data

Definitions of each series and notes on the data are contained in later sections of these notes describing each set of data. For detailed descriptions of each data series, see BLS *Handbook of Methods,* Volumes I and II, Bulletins 2134–1 and 2134–2 (Bureau of Labor Statistics, 1982 and 1984, respectively), as well as the additional bulletins, articles, and other publications noted in the separate sections of the *Review*'s "Current Labor Statistics Notes." Historical data for many series are provided in the *Handbook of Labor Statistics, Bulletin 2217* (Bureau of Labor Statistics, 1985). Users may also wish to consult *Major Programs, Bureau of Labor Statistics,* Report 718 (Bureau of Labor Statistics, 1985).

EMPLOYMENT DATA
(Tables 1; 4–21)

Household survey data

Description of the series

EMPLOYMENT DATA in this section are obtained from the Current Population Survey, a program of personal interviews conducted monthly by the Bureau of the Census for the Bureau of Labor Statistics. The sample consists of about 59,500 households selected to represent the U.S. population 16 years of age and older. Households are interviewed on a rotating basis, so that three-fourths of the sample is the same for any 2 consecutive months.

Definitions

Employed persons include (1) all civilians who worked for pay any time during the week which includes the 12th day of the month or who worked unpaid for 15 hours or more in a family-operated enterprise and (2) those who were temporarily absent from their regular jobs because of illness, vacation, industrial dispute, or similar reasons. Members of the Armed Forces stationed in the United States are also included in the employed total. A person working at more than one job is counted only in the job at which he or she worked the greatest number of hours.

Unemployed persons are those who did not work during the survey week, but were available for work except for temporary illness and had looked for jobs within the preceding 4 weeks. Persons who did not look for work because they were on layoff or waiting to start new jobs within the next 30 days are also counted among the unemployed. The **overall unemployment rate** represents the number unemployed as a percent of the labor force, including the resident Armed Forces. The **civilian unemployment rate** represents the number unemployed as a percent of the civilian labor force.

The **labor force** consists of all employed or unemployed civilians plus members of the Armed Forces stationed in the United States. Persons **not in the labor force** are those not classified as employed or unemployed; this group includes persons who are retired, those engaged in their own housework, those not working while attending school, those unable to work because of long-term illness, those discouraged from seeking work because of personal or job market factors, and those who are voluntarily idle. The **noninstitutional population** comprises all persons 16 years of age and older who are not inmates of penal or mental institutions, sanitariums, or homes for the aged, infirm, or needy, and members of the Armed Forces stationed in the United States. The **labor force participation rate** is the proportion of the noninstitutional populaton that is in the labor force. The **employment-population ratio** is total employment (including the resident Armed Forces) as a percent of the noninstitutional population.

Notes on the data

From time to time, and especially after a decennial census, adjustments are made in the Current Population Survey figures to correct for estimating errors during the preceding years. These adjustments affect the comparability of historical data. A description of these adjustments and their effect on the various data series appear in the Explanatory Notes of *Employment and Earnings.*

Data in tables 4–10 are seasonally adjusted, based on the seasonal experience through December 1985.

Additional sources of information

For detailed explanations of the data, see BLS *Handbook of Methods*, Bulletin 2134–1 (Bureau of Labor Statistics, 1982), chapter 1, and for additional data, *Handbook of Labor Statistics*, Bulletin 2217 (Bureau of Labor Statistics, 1985). A detailed description of the Current Population Survey as well as additional data are available in the monthly Bureau of Labor Statistics periodical, *Employment and Earnings*. Historical data from 1948 to 1981 are available in *Labor Force Statistics Derived from the Current Population Survey: A Databook*, Vols. I and II, Bulletin 2096 (Bureau of Labor Statistics, 1982).

A comprehensive discussion of the differences between household and establishment data on employment appears in Gloria P. Green, "Comparing employment estimates from household and payroll surveys," *Monthly Labor Review,* December 1969, pp. 9–20.

Establishment survey data

Description of the series

EMPLOYMENT, HOURS, AND EARNINGS DATA in this section are compiled from payroll records reported monthly on a voluntary basis to the Bureau of Labor Statistics and its cooperating State agencies by more than 250,000 establishments representing all industries except agriculture. In most industries, the sampling probabilities are based on the size of the establishment; most large establishments are therefore in the sample. (An establishment is not necessarily a firm; it may be a branch plant, for example, or warehouse.) Self-employed persons and others not on a regular civilian payroll are outside the scope of the survey because they are excluded from establishment records. This largely accounts for the difference in employment figures between the household and establishment surveys.

Definitions

An **establishment** is an economic unit which produces goods or services (such as a factory or store) at a single location and is engaged in one type of economic activity.

Employed persons are all persons who received pay (including holiday

and sick pay) for any part of the payroll period including the 12th of the month. Persons holding more than one job (about 5 percent of all persons in the labor force) are counted in each establishment which reports them.

Production workers in manufacturing include working supervisors and all nonsupervisory workers closely associated with production operations. Those workers mentioned in tables 12–17 include production workers in manufacturing and mining; construction workers in construction; and nonsupervisory workers in the following industries: transportation and public utilities; wholesale and retail trade; finance, insurance, and real estate; and services. These groups account for about four-fifths of the total employment on private nonagricutural payrolls.

Earnings are the payments production or nonsupervisory workers receive during the survey period, including premium pay for overtime or late-shift work but excluding irregular bonuses and other special payments. **Real earnings** are earnings adjusted to reflect the effects of changes in consumer prices. The deflator for this series is derived from the Consumer Price Index for Urban Wage Earner and Clerical Workers (CPI-W). The **Hourly Earnings Index** is calculated from average hourly earnings data adjusted to exclude the effects of two types of changes that are unrelated to underlying wage-rate developments: fluctuations in overtime premiums in manufacturing (the only sector for which overtime data are available) and the effects of changes and seasonal factors in the proportion of workers in high-wage and low-wage industries.

Hours represent the average weekly hours of production or nonsupervisory workers for which pay was received and are different from standard or scheduled hours. **Overtime hours** represent the portion of gross average weekly hours which were in excess of regular hours and for which overtime premiums were paid.

The Diffusion Index, introduced in the May 1983 *Review*, represents the percent of 185 nonagricultural industries in which employment was rising over the indicated period. One-half of the industries with unchanged employment are counted as rising. In line with Bureau practice, data for the 1-, 3-, and 6-month spans are seasonally adjusted, while those for the 12-month span are unadjusted. The diffusion index is useful for measuring the dispersion of economic gains or losses and is also an economic indicator.

Notes on the data

Establishment data collected by the Bureau of Labor Statistics are periodically adjusted to comprehensive counts of employment (called "benchmarks"). The latest complete adjustment was made with the release of May 1986 data, published in the July 1986 issue of the *Review*. Consequently, data published in the *Review* prior to that issue are not necessarily comparable to current data. Unadjusted data have been revised back to April 1984; seasonally adjusted data have been revised back to January 1981. These revisions were published in the *Supplement to Employment and Earnings* (Bureau of Labor Statistics, 1986). Unadjusted data from April 1985 forward, and seasonally adjusted data from January 1982 forward are subject to revision in future benchmarks.

Additional sources of information

Detailed data from the establishment survey are published monthly in the BLS periodical, *Employment and Earnings*. Earlier comparable unadjusted and seasonally adjusted data are published in *Employment, Hours, and Earnings, United States, 1909–84*, Bulletin 1312–12 (Bureau of Labor Statistics, 1985) and its annual supplement. For a detailed discussion of the methodology of the survey, see *BLS Handbook of Methods*, Bulletin 2134–1 (Bureau of Labor Statistics, 1982), chapter 2. For additional data, see *Handbook of Labor Statistics*, Bulletin 2217 (Bureau of Labor Statistics, 1985).

A comprehensive discussion of the differences between household and establishment data on employment appears in Gloria P. Green, "Comparing employment estimates from household and payroll surveys," *Monthly Labor Review*, December 1969, pp. 9–20.

Unemployment data by State

Description of the series

Data presented in this section are obtained from two major sources—the Current Population Survey (CPS) and the Local Area Unemployment Statistics (LAUS) program, which is conducted in cooperation with State employment security agencies.

Monthly estimates of the labor force, employment, and unemployment for States and sub-State areas are a key indicator of local economic conditions and form the basis for determining the eligibility of an area for benefits under Federal economic assistance programs such as the Job Training Partnership Act and the Public Works and Economic Development Act. Insofar as possible, the concepts and definitions underlying these data are those used in the national estimates obtained from the CPS.

Notes on the data

Data refer to State of residence. Monthly data for 11 States—California, Florida, Illinois, Massachusetts, Michigan, New York, New Jersey, North Carolina, Ohio, Pennsylvania, and Texas—are obtained directly from the CPS, because the size of the sample is large enough to meet BLS standards of reliability. Data for the remaining 39 States and the District of Columbia are derived using standardized procedures established by BLS. Once a year, estimates for the 11 States are revised to new population controls. For the remaining States and the District of Columbia, data are benchmarked to annual average CPS levels.

Additional sources of information

Information on the concepts, definitions, and technical procedures used to develop labor force data for States and sub-State areas as well as additional data on sub-States are provided in the monthly Bureau of Labor Statistics periodical, *Employment and Earnings*, and the annual report, *Geographic Profile of Employment and Unemployment* (Bureau of Labor Statistics). See also *BLS Handbook of Methods*, Bulletin 2134–1 (Bureau of Labor Statistics, 1982), chapter 4.

COMPENSATION AND WAGE DATA

(Tables 1–3; 22–29)

COMPENSATION AND WAGE DATA are gathered by the Bureau from business establishments, State and local governments, labor unions, collective bargaining agreements on file with the Bureau, and secondary sources.

Employment Cost Index

Description of the series

The **Employment Cost Index** (ECI) is a quarterly measure of the rate of change in compensation per hour worked and includes wages, salaries, and employer costs of employee benefits. It uses a fixed market basket of labor—similar in concept to the Consumer Price Index's fixed market basket of goods and services—to measure change over time in employer costs of employing labor. The index is not seasonally adjusted.

Statistical series on total compensation costs and on wages and salaries are available for private nonfarm workers excluding proprietors, the self-employed, and household workers. Both series are also available for State and local government workers and for the civilian nonfarm economy, which consists of private industry and State and local government workers combined. Federal workers are excluded.

The Employment Cost Index probability sample consists of about 2,200 private nonfarm establishments providing about 12,000 occupational observations and 700 State and local government establishments providing

3,500 occupational observations selected to represent total employment in each sector. On average, each reporting unit provides wage and compensation information on five well-specified occupations. Data are collected each quarter for the pay period including the 12th day of March, June, September, and December.

Fixed employment weights from the 1970 Census of Population are used each quarter to calculate the indexes for civilian, private, and State and local governments. These fixed weights, also used to derive all of the industry and occupation series indexes, ensure that changes in these indexes reflect only changes in compensation, not employment shifts among industries or occupations with different levels of wages and compensation. For the bargaining status, region, and metropolitan/nonmetropolitan area series, however, employment data by industry and occupation are not available from the census. Instead, the 1970 employment weights are reallocated within these series each quarter based on the current sample. Therefore, these indexes are not strictly comparable to those for the aggregate, industry, and occupation series.

Definitions

Total compensation costs include wages, salaries, and the employer costs for employee benefits.

Wages and salaries consist of earnings before payroll deductions, including production bonuses, incentive earnings, commissions, and cost-of-living adjustments.

Benefits include the cost to employers for paid leave, supplemental pay (including nonproduction bonuses), insurance, retirement and savings plans, and legally required benefits (such as social security, workers' compensation, and unemployment insurance).

Excluded from wages and salaries and employee benefits are such items as payment-in-kind, free room and board, and tips.

Notes on the data

The Employment Cost Index data series began in the fourth quarter of 1975, with the quarterly percent change in wages and salaries in the private nonfarm sector. Data on employer costs for employee benefits were included in 1980 to produce, when combined with the wages and salaries series, a measure of the percent change in employer costs for employee total compensation. State and local government units were added to the ECI coverage in 1981, providing a measure of total compensation change in the *civilian* nonfarm economy (excluding Federal employees). Historical indexes (June 1981=100) of the quarterly rates of change are presented in the May issue of the BLS monthly periodical, *Current Wage Developments*.

Additional sources of information

For a more detailed discussion of the Employment Cost Index, see Chapter 11, "The Employment Cost Index," in the *Handbook of Methods*, Bulletin 2134–1 (Bureau of Labor Statistics, 1982), chapter 11, and the following *Monthly Labor Review* articles: "Employment Cost Index: a measure of change in the 'price of labor'," July 1975; "How benefits will be incorporated into the Employment Cost Index," January 1978; "Estimation procedures for the Employment Cost Index," May 1982; and "Introducing new weights for the Employment Cost Index," June 1985.

Data on the ECI are also available in BLS quarterly press releases issued in the month following the reference months of March, June, September, and December; and from the *Handbook of Labor Statistics*, Bulletin 2217 (Bureau of Labor Statistics, 1985).

Collective bargaining settlements

Description of the series

Collective bargaining settlements data provide statistical measures of negotiated adjustments (increases, decreases, and freezes) in compensation (wages and benefits costs) and wages alone, quarterly for private industry and semiannually for State and local government. Compensation measures cover all collective bargaining situations involving 5,000 workers or more and wage measures cover all situations involving 1,000 workers or more. These data, covering private nonagricultural industries and State and local governments, are calculated using information obtained from bargaining agreements on file with the Bureau, parties to the agreements, and secondary sources, such as newspaper accounts. The data are not seasonally adjusted.

Settlement data are measured in terms of future specified adjustments: those that will occur within 12 months after contract ratification—first year—and all adjustments that will occur over the life of the contract expressed as an average annual rate. Adjustments are worker weighted. Both first-year and over-the-life measures exclude wage changes that may occur under cost-of-living clauses that are triggered by future movements in the Consumer Price Index.

Effective wage adjustments measure all adjustments occurring in the reference period, regardless of the settlement date. Included are changes from settlements reached during the period, changes deferred from contracts negotiated in earlier periods, and changes under cost-of-living adjustment clauses. Each wage change is worker weighted. The changes are prorated over all workers under agreements during the reference period yielding the average adjustment.

Definitions

Wage rate changes are calculated by dividing newly negotiated wages by the average hourly earnings, excluding overtime, at the time the agreement is reached. Compensation changes are calculated by dividing the change in the value of the newly negotiated wage and benefit package by existing average hourly compensation, which includes the cost of previously negotiated benefits, legally required social insurance programs, and average hourly earnings.

Compensation changes are calculated by placing a value on the benefit portion of the settlements at the time they are reached. The cost estimates are based on the assumption that conditions existing at the time of settlement (for example, methods of financing pensions or composition of labor force) will remain constant. The data, therefore, are measures of negotiated changes and not of total changes in employer cost.

Contract duration runs from the effective date of the agreement to the expiration date or first wage reopening date, if applicable. Average annual percent changes over the contract term take account of the compounding of successive changes.

Notes on the data

Care should be exercised in comparing the size and nature of the settlements in State and local government with those in the private sector because of differences in bargaining practices and settlement characteristics. A principal difference is the incidence of cost-of-living adjustment (COLA) clauses which cover only about 2 percent of workers under a few local government settlements, but cover 50 percent of workers under private sector settlements. Agreements without COLA's tend to provide larger specified wage increases than those with COLA's. Another difference is that State and local government bargaining frequently excludes pension benefits which are often prescribed by law. In the private sector, in contrast, pensions are typically a bargaining issue.

Additional sources of information

For a more detailed discussion on the series, see of the BLS *Handbook of Methods*, Bulletin 2134–1 (Bureau of Labor Statistics, 1982), chapter 10. Comprehensive data are published in press releases issued quarterly (in January, April, July, and October) for private industry, and semi-

annually (in February and August) for State and local government. Historical data and additional detailed tabulations for the prior calendar year appear in the April issue of the BLS monthly periodical, *Current Wage Developments*.

Work stoppages

Description of the series

Data on **work stoppages** measure the number and duration of major strikes or lockouts (involving 1,000 workers or more) occurring during the month (or year), the number of workers involved, and the amount of time lost because of stoppage.

Data are largely from newspaper accounts and cover only establishments directly involved in a stoppage. They do not measure the indirect or secondary effect of stoppages on other establishments whose employees are idle owing to material shortages or lack of service.

Definitions

Number of stoppages: The number of strikes and lockouts involving 1,000 workers or more and lasting a full shift or longer.

Workers involved: The number of workers directly involved in the stoppage.

Number of days idle: The aggregate number of work days lost by workers involved in the stoppages.

Days of idleness as a percent of estimated working time: Aggregate work days lost as a percent of the aggregate number of standard work days in the period multiplied by total employment in the period.

Notes on the data

This series is not comparable with the one terminated in 1981 that covered strikes involving six workers or more.

Additional sources of information

Data for each calendar year are reported in a BLS press release issued in the first quarter of the following year. Monthly data appear in the BLS monthly periodical, *Current Wage Developments*. Historical data appear in the BLS *Handbook of Labor Statistics*.

Other compensation data

Other BLS data on pay and benefits, not included in the Current Labor Statistics section of the *Monthly Labor Review*, appear in and consist of the following:

Industry Wage Surveys provide data for specific occupations selected to represent an industry's wage structure and the types of activities performed by its workers. The Bureau collects information on weekly work schedules, shift operations and pay differentials, paid holiday and vacation practices, and information on incidence of health, insurance, and retirement plans. Reports are issued throughout the year as the surveys are completed. Summaries of the data and special analyses also appear in the *Monthly Labor Review*.

Area Wage Surveys annually provide data for selected office, clerical, professional, technical, maintenance, toolroom, powerplant, material movement, and custodial occupations common to a wide variety of industries in the areas (labor markets) surveyed. Reports are issued throughout the year as the surveys are completed. Summaries of the data and special analyses also appear in the *Review*.

The National Survey of Professional, Administrative, Technical, and Clerical Pay provides detailed information annually on salary levels and distributions for the types of jobs mentioned in the survey's title in private employment. Although the definitions of the jobs surveyed reflect the duties and responsibilities in private industry, they are designed to match specific pay grades of Federal white-collar employees under the General Schedule pay system. Accordingly, this survey provides the legally required information for comparing the pay of salaried employees in the Federal civil service with pay in private industry. (See Federal Pay Comparability Act of 1970, 5 U.S.C. 5305.) Data are published in a BLS news release issued in the summer and in a bulletin each fall; summaries and analytical articles also appear in the *Review*.

Employee Benefits Survey provides nationwide information on the incidence and characteristics of employee benefit plans in medium and large establishments in the United States, excluding Alaska and Hawaii. Data are published in an annual BLS news release and bulletin, as well as in special articles appearing in the *Review*.

PRICE DATA

(Tables 2; 30–41)

PRICE DATA are gathered by the Bureau of Labor Statistics from retail and primary markets in the United States. Price indexes are given in relation to a base period (1967 = 100, unless otherwise noted).

Consumer Price Indexes

Description of the series

The **Consumer Price Index** (CPI) is a measure of the average change in the prices paid by urban consumers for a fixed market basket of goods and services. The CPI is calculated monthly for two population groups, one consisting only of urban households whose primary source of income is derived from the employment of wage earners and clerical workers, and the other consisting of all urban households. The wage earner index (CPI-W) is a continuation of the historic index that was introduced well over a half-century ago for use in wage negotiations. As new uses were developed for the CPI in recent years, the need for a broader and more representative index became apparent. The all urban consumer index (CPI-U) introduced in 1978 is representative of the 1972–73 buying habits of about 80 percent of the noninstitutional population of the United States at that time, compared with 40 percent represented in the CPI-W. In addition to wage earners and clerical workers, the CPI-U covers professional, managerial, and technical workers, the self-employed, short-term workers, the unemployed, retirees, and others not in the labor force.

The CPI is based on prices of food, clothing, shelter, fuel, drugs, transportation fares, doctors' and dentists' fees, and other goods and services that people buy for day-to-day living. The quantity and quality of these items are kept essentially unchanged between major revisions so that only price changes will be measured. All taxes directly associated with the purchase and use of items are included in the index.

Data collected from more than 24,000 retail establishments and 24,000 tenants in 85 urban areas across the country are used to develop the "U.S. city average." Separate estimates for 28 major urban centers are presented in table 31. The areas listed are as indicated in footnote 1 to the table. The area indexes measure only the average change in prices for each area since the base period, and do not indicate differences in the level of prices among cities.

Notes on the data

In January 1983, the Bureau changed the way in which homeownership costs are measured for the CPI-U. A rental equivalence method replaced the

asset-price approach to homeownership costs for that series. In January 1985, the same change was made in the CPI-W. The central purpose of the change was to separate shelter costs from the investment component of homeownership so that the index would reflect only the cost of shelter services provided by owner-occupied homes.

Additional sources of information

For a discussion of the general method for computing the CPI, see *BLS Handbook of Methods, Volume II, The Consumer Price Index*, Bulletin 2134–2 (Bureau of Labor Statistics, 1984). The recent change in the measurement of homeownership costs is discussed in Robert Gillingham and Walter Lane, "Changing the treatment of shelter costs for homeowners in the CPI," *Monthly Labor Review*, June 1982, pp. 9–14.

Additional detailed CPI data and regular analyses of consumer price changes are provided in the *CPI Detailed Report*, a monthly publication of the Bureau. Historical data for the overall CPI and for selected groupings may be found in the *Handbook of Labor Statistics*, Bulletin 2217 (Bureau of Labor Statistics, 1985).

Producer price indexes

Description of the series

Producer Price Indexes (PPI) measure average changes in prices received in primary markets of the United States by producers of commodities in all stages of processing. The sample used for calculating these indexes currently contains about 3,200 commodities and about 60,000 quotations per month selected to represent the movement of prices of all commodities produced in the manufacturing, agriculture, forestry, fishing, mining, gas and electricity, and public utilities sectors. The stage of processing structure of Producer Price Indexes organizes products by class of buyer and degree of fabrication (that is, finished goods, intermediate goods, and crude materials). The traditional commodity structure of PPI organizes products by similarity of end-use or material composition.

To the extent possible, prices used in calculating Producer Price Indexes apply to the first significant commercial transaction in the United States from the production or central marketing point. Price data are generally collected monthly, primarily by mail questionnaire. Most prices are obtained directly from producing companies on a voluntary and confidential basis. Prices generally are reported for the Tuesday of the week containing the 13th day of the month.

Since January 1976, price changes for the various commodities have been averaged together with implicit quantity weights representing their importance in the total net selling value of all commodities as of 1972. The detailed data are aggregated to obtain indexes for stage-of-processing groupings, commodity groupings, durability-of-product groupings, and a number of special composite groups. All Producer Price Index data are subject to revision 4 months after original publication.

Notes on the data

Beginning with the January 1986 issue, the *Review* is no longer presenting tables of Producer Price Indexes for commodity groupings, special composite groups, or SIC industries. However, these data will continue to be presented in the Bureau's monthly publication *Producer Price Indexes*. Series on the net output of major mining and manufacturing industry groups will appear in the *Review* starting with data for July 1986.

The Bureau has completed the first major stage of its comprehensive overhaul of the theory, methods, and procedures used to construct the Producer Price Indexes. Changes include the replacement of judgment sampling with probability sampling techniques; expansion to systematic coverage of the net output of virtually all industries in the mining and manufacturing sectors; a shift from a commodity to an industry orientation; the exclusion of imports from, and the inclusion of exports in, the survey universe; and the respecification of commodities priced to conform to Bureau of the Census definitions. These and other changes have been phased in gradually since 1978. The result is a system of indexes that is easier to use in conjunction with data on wages, productivity, and employment and other series that are organized in terms of the Standard Industrial Classification and the Census product class designations.

Additional sources of information

For a discussion of the methodology for computing Producer Price Indexes, see *BLS Handbook of Methods*, Bulletin 2134–1 (Bureau of Labor Statistics, 1982), chapter 7.

Additional detailed data and analyses of price changes are provided monthly in *Producer Price Indexes*. Selected historical data may be found in the *Handbook of Labor Statistics*, Bulletin 2217 (Bureau of Labor Statistics, 1985).

International price indexes

Description of the series

The BLS **International Price Program** produces quarterly export and import price indexes for nonmilitary goods traded between the United States and the rest of the world. The export price index provides a measure of price change for all products sold by U.S. residents to foreign buyers. ("Residents" is defined as in the national income accounts: it includes corporations, businesses, and individuals but does not require the organizations to be U.S. owned nor the individuals to have U.S. citizenship.) The import price index provides a measure of price change for goods purchased from other countries by U.S. residents. With publication of an all-import index in February 1983 and an all-export index in February 1984, all U.S. merchandise imports and exports now are represented in these indexes. The reference period for the indexes is 1977 = 100, unless otherwise indicated.

The product universe for both the import and export indexes includes raw materials, agricultural products, semifinished manufactures, and finished manufactures, including both capital and consumer goods. Price data for these items are collected quarterly by mail questionnaire. In nearly all cases, the data are collected directly from the exporter or importer, although in a few cases, prices are obtained from other sources.

To the extent possible, the data gathered refer to prices at the U.S. border for exports and at either the foreign border or the U.S. border for imports. For nearly all products, the prices refer to transactions completed during the first 2 weeks of the third month of each calendar quarter—March, June, September, and December. Survey respondents are asked to indicate all discounts, allowances, and rebates applicable to the reported prices, so that the price used in the calculation of the indexes is the acual price for which the product was bought or sold.

In addition to general indexes of prices for U.S. exports and imports, indexes are also published for detailed product categories of exports and imports. These categories are defined by the 4- and 5-digit level of detail of the Standard Industrial Trade Classification System (SITC). The calculation of indexes by SITC category facilitates the comparison of U.S. price trends and sector production with similar data for other countries. Detailed indexes are also computed and published on a Standard Industrial Classification (SIC-based) basis, as well as by end-use class.

Notes on the data

The export and import price indexes are weighted indexes of the Laspeyeres type. Price relatives are assigned equal importance within each weight category and are then aggregated to the SITC level. The values assigned to each weight category are based on trade value figures compiled

by the Bureau of the Census. The trade weights currently used to compute both indexes relate to 1980.

Because a price index depends on the same items being priced from period to period, it is necessary to recognize when a product's specifications or terms of transaction have been modified. For this reason, the Bureau's quarterly questionnaire requests detailed descriptions of the physical and functional characteristics of the products being priced, as well as information on the number of units bought or sold, discounts, credit terms, packaging, class of buyer or seller, and so forth. When there are changes in either the specifications or terms of transaction of a product, the dollar value of each change is deleted from the total price change to obtain the "pure" change. Once this value is determined, a linking procedure is employed which allows for the continued repricing of the item.

For the export price indexes, the preferred pricing basis is f.a.s. (free alongside ship) U.S. port of exportation. When firms report export prices f.o.b. (free on board), production point information is collected which enables the Bureau to calculate a shipment cost to the port of exportation. An attempt is made to collect two prices for imports. The first is the import price f.o.b. at the foreign port of exportation, which is consistent with the basis for valuation of imports in the national accounts. The second is the import price c.i.f. (cost, insurance, and freight) at the U.S. port of importation, which also includes the other costs associated with bringing the product to the U.S. border. It does not, however, include duty charges.

Additional sources of information

For a discussion of the general method of computing International Price Indexes, see *BLS Handbook of Methods*, Bulletin 2134–1 (Bureau of Labor Statistics, 1982), chapter 8.

Additional detailed data and analyses of international price developments are presented in the Bureau's quarterly publication *U.S. Import and Export Price Indexes* and in occasional *Monthly Labor Review* articles prepared by BLS analysts. Selected historical data may be found in the *Handbook of Labor Statistics*, Bulletin 2217 (Bureau of Labor Statistics, 1985).

PRODUCTIVITY DATA
(Tables 2; 42–47)

U. S. productivity and related data

Description of the series

The productivity measures relate real physical output to real input. As such, they encompass a family of measures which include single factor input measures, such as output per unit of labor input (output per hour) or output per unit of capital input, as well as measures of multifactor productivity (output per unit of labor and capital inputs combined). The Bureau indexes show the change in output relative to changes in the various inputs. The measures cover the business, nonfarm business, manufacturing, and nonfinancial corporate sectors.

Corresponding indexes of hourly compensation, unit labor costs, unit nonlabor payments, and prices are also provided.

Definitions

Output per hour of all persons (labor productivity) is the value of goods and services in constant prices produced per hour of labor input. **Output per unit of capital services** (capital productivity) is the value of goods and services in constant dollars produced per unit of capital services input.

Multifactor productivity is the ratio output per unit of labor and capital inputs combined. Changes in this measure reflect changes in a number of factors which affect the production process such as changes in technology, shifts in the composition of the labor force, changes in capacity utilization, research and development, skill and efforts of the work force, management, and so forth. Changes in the output per hour measures reflect the impact of these factors as well as the substitution of capital for labor.

Compensation per hour is the wages and salaries of employees plus employers' contributions for social insurance and private benefit plans, and the wages, salaries, and supplementary payments for the self-employed (except for nonfinancial corporations in which there are no self-employed)—the sum divided by hours paid for. **Real compensation per hour** is compensation per hour deflated by the change in the Consumer Price Index for All Urban Consumers.

Unit labor costs is the labor compensation costs expended in the production of a unit of output and is derived by dividing compensation by output. **Unit nonlabor payments** include profits, depreciation, interest, and indirect taxes per unit of output. They are computed by subtracting compensation of all persons from current dollar value of output and dividing by output. **Unit nonlabor costs** contain all the components of unit nonlabor payments *except* unit profits.

Unit profits include corporate profits and the value of inventory adjustments per unit of output.

Hours of all persons are the total hours paid of payroll workers, self-employed persons, and unpaid family workers.

Capital services is the flow of services from the capital stock used in production. It is developed from measures of the net stock of physical assets—equipment, structures, land, and inventories—weighted by rental prices for each type of asset.

Labor and capital inputs combined are derived by combining changes in labor and capital inputs with weights which represent each component's share of total output. The indexes for capital services and combined units of labor and capital are based on changing weights which are averages of the shares in the current and preceding year (the Tornquist index-number formula).

Notes on the data

Output measures for the business sector and the nonfarm businesss sector exclude the constant dollar value of owner-occupied housing, rest of world, households and institutions, and general government output from the constant dollar value of gross national product. The measures are derived from data supplied by the Bureau of Economic Analysis, U.S. Department of Commerce, and the Federal Reserve Board. Quarterly manufacturing output indexes are adjusted by the Bureau of Labor Statistics to annual estimates of output (gross product originating) from the Bureau of Economic Analysis. Compensation and hours data are developed from data of the Bureau of Labor Statistics and the Bureau of Economic Analysis.

The productivity and associated cost measures in tables 42–44 describe the relationship between output in real terms and the labor time and capital services involved in its production. They show the changes from period to period in the amount of goods and services produced per unit of input. Although these measures relate output to hours and capital services, they do not measure the contributions of labor, capital, or any other specific factor of production. Rather, they reflect the joint effect of many influences, including changes in technology; capital investment; level of output; utilization of capacity, energy, and materials; the organization of production; managerial skill; and the characteristics and efforts of the work force.

Additional sources of information

Descriptions of methodology underlying the measurement of output per hour and multifactor productivity are found in the *BLS Handbook of Methods*, Bulletin 2134–1 (Bureau of Labor Statistics, 1982), chapter 13. Historical data for selected industries are provided in the Bureau's *Handbook of Labor Statistics*, 1985, Bulletin 2217.

International comparisons

Description of the series

Comparative measures of labor force, employment, and unemployment (tables 45 and 46) are prepared regularly for the United States, Canada, Australia, Japan, France, Germany, Great Britain, Italy, the Netherlands, and Sweden. Unemployment rates, approximating U.S. concepts, are prepared monthly for most of the countries; the other measures, annually.

The Bureau of Labor Statistics also prepares international comparisons of manufacturing labor productivity and labor costs (table 47) that cover the United States and 11 foreign countries—those listed above plus Belgium and Norway. These measures are limited to trend comparisons; that is, intercountry series of changes over time, rather than level comparisons because reliable international comparisons of the levels of manufacturing are unavailable. The U.S. measures are described in the notes on U.S. productivity measurement; the measures for foreign countries are compiled from various national and international data sources.

Definitions

Output measures are constant value output (value added) from the national accounts of each country, except for those for Japan prior to 1970 and for the Netherlands for 1969 forward, which are indexes of industrial production. The national accounting methods for measuring real output differ considerably among the 12 countries, but the use of different procedures does not, in itself, connote lack of comparability—rather, it reflects differences among countries in the availability and reliability of underlying data series.

Hours and compensation measures refer to all employed persons including the self-employed in the United States and Canada, and to all wage and salary employees in the other countries. *Hours* refer to hours *paid* in the United States, hours *worked* in the other countries. *Compensation (labor costs)* includes not only all payments made directly to employees and employer expenditures for social insurance and private benefit plans, but changes in significant employment or payroll taxes that are not compensation to employees but are labor costs to employers (France, Sweden, and the United Kingdom). Self-employed workers are included in the U.S. and Canadian figures by assuming that their hourly compensation is equal to the average for wage and salary employees.

Notes on the data

The data for the foreign countries in tables 45 and 46 have been adjusted, where necessary, for greater comparability with U.S. definitions of employment and unemployment. The adjusted statistics have been adapted to the age at which compulsory schooling ends in each country. Therefore, the adjusted statistics relate to the civilian population age 16 and over in the United States, France, and Sweden, and from 1973 forward, Great Britain; 15 and over in Canada, Australia, Japan, Germany, and the Netherlands; and 14 and over in Italy. Prior to 1973, the data for Great Britain related to persons age 15 and over. The institutional population is included in the denominator of the labor force participation rates and employment-population ratios for Japan and Germany.

For most of the countries in table 47, the measures refer to total manufacturing as defined by the International Standard Industrial Classification. However, the measures for France (beginning 1959), Italy (beginning 1970), and the United Kingdom (beginning 1976) refer to manufacturing and mining less energy-related products. For all countries, manufacturing includes the activities of government enterprises.

In addition, for all countries, preliminary estimates for recent years are generally based on current indicators of manufacturing output, employment and hours, and hourly compensation until national accounts and other statistics used for the long-term measures become available.

Additional sources of information

For further information, see *International Comparisons of Unemployment*, Bulletin 1979 (Bureau of Labor Statistics, 1978), Appendix B and Supplements to Appendix B. Additional detail is also found in the BLS *Handbook of Methods*, Bulletin 2134–1, (Bureau of Labor Statistics, 1982), chapter 16. Additional international comparison statistics are available in the *Handbook of Labor Statistics* Bulletin 2217 (Bureau of Labor Statistics, 1985). The most recent statistics are presented and analyzed annually in the *Monthly Labor Review*, typically in the December issue (for the previous year) and in February.

OCCUPATIONAL INJURY AND ILLNESS DATA

(Table 48)

Description of the series

The Annual Survey of Occupational Injuries and Illnesses is designed to collect data on injuries and illnesses based on records which employers in the following industries maintain under the Occupational Safety and Health Act of 1970: agriculture, forestry, and fishing; oil and gas extraction; construction; manufacturing; transportation and public utilities; wholesale and retail trade; finance, insurance, and real estate; and services. Excluded from the survey are self-employed individuals, farmers with fewer than 11 employees, employers regulated by other Federal safety and health laws, and Federal, State, and local government agencies.

Because the survey is a Federal–State cooperative program and the data must meet the needs of participating State agencies, an independent sample is selected for each State. The sample is selected to represent all private industries in the States and territories. The sample size for the survey is dependent upon (1) the characteristics for which estimates are needed; (2) the industries for which estimates are desired; (3) the characteristics of the population being sampled; (4) the target reliability of the estimates; and (5) the survey design employed.

While there are many characteristics upon which the sample design could be based, the total recorded case incidence rate is used because it is one of the most important characteristics and the least variable; therefore, it requires the smallest sample size.

The survey is based on stratified random sampling with a Neyman allocation and a ratio estimator. The characteristics used to stratify the establishments are the Standard Industrial Classification (SIC) code and size of employment.

Definitions

Recordable occupational injuries and illnesses are: (1) occupational deaths, regardless of the time between injury and death, or the length of the illness; or (2) nonfatal occupational illnesses; or (3) nonfatal occupational injuries which involve one or more of the following: loss of consciousness, restriction of work or motion, transfer to another job, or medical treatment (other than first aid).

Occupational injury is any injury such as a cut, fracture, sprain, amputation, and so forth, which results from a work accident or from exposure involving a single incident in the work environment.

Occupational illness is an abnormal condition or disorder, other than one resulting from an occupational injury, caused by exposure to environmental factors associated with employment. It includes acute and chronic illnesses or disease which may be caused by inhalation, absorption, ingestion, or direct contact.

Lost workday cases are cases which involve days away from work, or days of restricted work activity, or both.

Lost workday cases involving restricted work activity are those cases which result in restricted work activity only.

Lost workdays away from work are the number of workdays (consecutive or not) on which the employee would have worked but could not because of occupational injury or illness.

Lost workdays—restricted work activity are the number of workdays (consecutive or not) on which, because of injury or illness: (1) the employee was assigned to another job on a temporary basis; or (2) the employee worked at a permanent job less than full time; or (3) the employee worked at a permanently assigned job but could not perform all duties normally connected with it.

The number of days away from work or days of restricted work activity does not include the day of injury or onset of illness or any days on which the employee would not have worked even though able to work.

Incidence rates represent the number of injuries and/or illnesses or lost workdays per 100 full-time workers.

Notes on the data

Estimates are made for industries and employment-size classes and for severity classification: fatalities, lost workday cases, and nonfatal cases without lost workdays. Lost workday cases are separated into those where the employee would have worked but could not and those in which work activity was restricted. Estimates of the number of cases and the number of days lost are made for both categories.

Most of the estimates are in the form of incidence rates, defined as the number of injuries and illnesses, or lost workdays, per 100 full-time employees. For this purpose, 200,000 employee hours represent 100 employee years (2,000 hours per employee). Only a few of the available measures are included in the *Handbook of Labor Statistics*. Full detail is presented in the annual bulletin, *Occupational Injuries and Illnesses in the United States, by Industry*.

Comparable data for individual States are available from the BLS Office of Occupational Safety and Health Statistics.

Mining and railroad data are furnished to BLS by the Mine Safety and Health Administration and the Federal Railroad Administration, respectively. Data from these organizations are included in BLS and State publications. Federal employee experience is compiled and published by the Occupational Safety and Health Administration. Data on State and local government employees are collected by about half of the States and territories; these data are not compiled nationally.

Additional sources of information

The Supplementary Data System provides detailed information describing various factors associated with work-related injuries and illnesses. These data are obtained from information reported by *employers* to State workers' compensation agencies. The Work Injury Report program examines selected types of accidents through an employee survey which focuses on the circumstances surrounding the injury. These data are not included in the *Handbook of Labor Statistics* but are available from the BLS Office of Occupational Safety and Health Statistics.

The definitions of occupational injuries and illnesses and lost workdays are from *Recordkeeping Requirements under the Occupational Safety and Health Act of 1970*. For additional data, see *Occupational Injuries and Illnesses in the United States, by Industry*, annual Bureau of Labor Statistics bulletin; BLS *Handbook of Methods*, Bulletin 2134–1 (Bureau of Labor Statistics, 1982), chapter 17; *Handbook of Labor Statistics*, Bulletin 2217 (Bureau of Labor Statistics, 1985), pp. 411–14; annual reports in the *Monthly Labor Review*; and annual U.S. Department of Labor press releases.

1. Labor market indicators

Selected indicators	1984	1985	1984			1985				1986
			II	III	IV	I	II	III	IV	I
Employment data										
Employment status of the civilian noninstitutionalized population (household survey)[1]

---

[1] Cost (cents-per-hour worked) measured in the Employment Cost Index consists of wages, salaries, and employer cost of employee benefits.

[2] Consist of private industry workers (excluding farm and household workers) and State and local government (excluding Federal Government) workers.

[3] Consists of legislative, judicial, administrative, and regulatory activities.

[4] Includes, for example, library, social, and health services.

---

[1] The indexes are calculated differently from those for the occupation and industry groups. For a detailed description of the index calculation, see the *Monthly Labor Review* Technical Note, "Estimation procedures for the Employment Cost Index," May 1982.

25. Specified compensation and wage adjustments from contract settlements, and effective wage adjustments, private industry collective bargaining situations covering 1,000 workers or more (in percent)

Measure	Annual average		Quarterly average							
			1984			1985				1986
	1984	1985	II	III	IV	I	II	III	IV	Ip
Specified adjustments:										
Total compensation [1] adjustments, [2] settlements covering 5,000 workers or more:										
First year of contract	3.6	2.6	3.5	2.7	3.7	3.6	3.5	2.0	2.0	0.3
Annual rate over life of contract	2.8	2.7	3.2	3.1	2.0	2.7	3.4	3.0	1.4	1.2
Wage adjustments, settlements covering 1,000 workers or more:										
First year of contract	2.4	2.3	2.6	2.1	2.3	3.3	2.5	2.0	2.1	.8
Annual rate over life of contract	2.4	2.7	2.7	2.6	1.5	3.2	2.8	3.1	1.9	1.6
Effective adjustments:										
Total effective wage adjustment [3]	3.7	3.3	.9	1.2	.7	.7	.8	1.2	.5	.6
From settlements reached in period	.8	.7	.1	.2	.3	.1	.2	.2	.1	.0
Deferred from settlements reached in earlier periods	2.0	1.8	.7	.7	.2	.6	.5	.5	.2	.4
From cost-of-living-adjustments clauses	.9	.7	.2	.3	.2	.1	.1	.4	.1	.2

---

[1] Compensation includes wages, salaries, and employers' cost of employee benefits when contract is negotiated.

[2] Adjustments are the net result of increases, decreases, and no changes in compensation or wages.

[3] Because of rounding total may not equal sum of parts.

p = preliminary.

26. Average specified compensation and wage adjustments, major collective bargaining settlements in private industry situations covering 1,000 workers or more during 4-quarter periods (in percent)

Measure	Average for four quarters ending–							
	1984			1985				1986
	II	III	IV	I	II	III	IV	Ip
Specified total compensation adjustments, settlements covering 5,000 workers or more, all industries:

[1] Data do not meet publication standards.

p = preliminary.

27. Average effective wage adjustments, private industry collective bargaining situations covering 1,000 workers or more during 4-quarter periods (in percent)

Effective wage adjustment	Average for four quarters ending–						
	1984		1985				1986
	III	IV	I	II	III	IV	I^p
For all workers:[1]							
Total	4.2	3.7	3.6	3.5	3.5	3.3	3.1
From settlements reached in period	1.0	.8	.7	.9	.9	.7	.6
Deferred from settlements reached in earlier period	2.1	2.0	2.2	1.9	1.8	1.8	1.7
From cost-of-living-adjustments clauses	1.2	.9	.7	.7	.8	.7	.8
For workers receiving changes:							
Total	5.0	4.4	4.5	4.2	4.3	4.1	4.0
From settlements reached in period	3.7	3.0	2.9	2.9	2.8	3.4	2.9
Deferred from settlements reached in earlier period	4.2	4.0	4.2	3.9	3.7	3.7	3.5
From cost-of-living-adjustments clauses	3.2	2.7	2.3	2.3	2.8	2.2	2.5

[1] Because of rounding total may not equal sum of parts.

^{p} = preliminary.

28. Specified compensation and wage adjustments from contract settlements, and effective wage adjustments, State and local government collective bargaining situations covering 1,000 workers or more (in percent)

Measure	Annual average		Second 6 months 1985^p
	1984	1985	
Specified adjustments:			
Total compensation[1] adjustments,[2] settlements covering 5,000 workers or more:			
First year of contract	5.2	4.2	3.8
Annual rate over life of contract	5.4	5.1	5.3
Wage adjustments, settlements covering 1,000 workers or more:			
First year of contract	4.8	4.6	4.4
Annual rate over life of contract	5.1	5.4	5.6
Effective adjustments:			
Total effective wage adjustment[3]	5.0	5.7	4.1
From settlements reached in period	1.9	4.1	3.2
Deferred from settlements reached in earlier periods	3.1	1.6	.9
From cost-of-living-adjustment clauses	(4)	(4)	(4)

[1] Compensation includes wages, salaries, and employers' cost of employee benefits when contract is negotiated.

[2] Adjustments are the net result of increases, decreases, and no changes in compensation or wages.

[3] Because of rounding total may not equal sum of parts.

[4] Less than 0.05 percent.

^{p} = preliminary.

29. Work stoppages involving 1,000 workers or more

Measure	Annual totals		1985								1986				
	1984	1985	May	June	July	Aug.	Sept.	Oct.	Nov.	Dec.	Jan.^{p}	Feb.^{p}	Mar.^{p}	Apr.^{p}	May^p
Number of stoppages:															
Beginning in period	62	54	2	2	9	8	11	6	3	2	4	3	3	4	5
In effect during period	68	61	8	8	13	18	20	20	13	9	7	7	9	9	10
Workers involved:															
Beginning in period (in thousands)	376.0	323.9	6.9	15.7	50.1	15.3	69.5	76.6	26.2	8.2	7.6	24.0	12.3	7.2	28.7
In effect during period (in thousands)	391.0	584.1	15.1	28.5	56.9	66.8	93.9	119.3	47.0	38.0	120	284	397	187	360
Days idle:															
Number (in thousands)	8,499.0	7,079.0	203.3	454.3	500.2	869.7	931.4	1,433.0	651.2	685.4	1,700	3,085	3,806	3,215	3,846
Percent of estimated working time[1]	.04	.03	.01	.02	.02	.04	.04	.06	.04	.03	1	2	2	2	2

[1] Agricultural and government employees are included in the total employed and total working time: private household, forestry, and fishery employees are excluded. An explanation of the measurement of idleness as a percentage of the total time worked is found in "'Total economy' measure of strike idleness," *Monthly Labor Review*, October 1968, pp. 54-56.

[1] Area is generally the Standard Metropolitan Statistical Area (SMSA), exclusive of farms. L.A.-Long Beach, Anaheim, Calif. is a combination of two SMSA's, and N.Y., N.Y.-Northeastern N.J. and Chicago, Ill.-Northwestern Ind. are the more extensive Standard Consolidated Areas. Area definitions are those established by the Office of Management and Budget in 1973, except for Denver-Boulder, Colo. which does not include Douglas County. Definitions do not include revisions made since 1973.

[2] Foods, fuels, and several other items priced every month in all areas; most other goods and services priced as indicated:

M - Every month.
1 - January, March, May, July, September, and November.
2 - February, April, June, August, October, and December.

[3] Regions are defined as the four Census regions.

The population size classes are aggregations of areas which have urban population as defined:

A-1 - More than 4,000,000.
A-2 - 1,250,000 to 4,000,000.
B - 385,000 to 1,250,000
C - 75,000 to 385,000.
D - Less than 75,000.

Population size class A is the aggregation of population size classes A-1 and A-2.

– Data not available.

NOTE: Local area CPI indexes are byproducts of the national CPI program. Because each local index is a small subset of the national index, it has a smaller sample size and is, therefore, subject to substantially more sampling and other measurement error than the national index. As a result, local area indexes show greater volatility than the national index, although their long-term trends are quite similar. Therefore, the Bureau of Labor Statistics strongly urges users to consider adopting the national average CPI for use in escalator clauses.

---

[1] Quarterly rates are for the first month of the quarter.

[2] Major changes in the Italian labor force survey, introduced in 1977, resulted in a large increase in persons enumerated as unemployed. However, many persons reported that they had not actively sought work in the past 30 days, and they have been provisionally excluded for comparability with U.S. concepts. Inclusion of such persons would more than double the Italian unemployment rate shown.

NOTE: Quarterly and monthly figures for France, Germany, and Great Britain are calculated by applying annual adjustment factors to current published data and therefore should be viewed as less precise indicators of unemployment under U.S. concepts than the annual figures.

46. Annual data: Employment status of the civilian working-age population, ten countries

---

[1] Total cases include fatalities.

[2] The incidence rates represent the number of injuries and illnesses or lost workdays per 100 full-time workers and were calculated as: (N/EH) X 200,000, where:

N = number of injuries and illnesses or lost workdays.

EH = total hours worked by all employees during calendar year.

200,000 = base for 100 full-time equivalent workers (working 40 hours per week, 50 weeks per year.)

[3] Excludes farms with fewer than 11 employees since 1976.

BLS Bulletins

Occupational Injuries and Illnesses in the United States by Industry, 1984. Bulletin 2259, 80 pp., $4.25 (GPO Stock No. 029-001-02900-4). Contains 1983 and 1984 data by industry on occupational injuries, illnesses, and fatalities in private sector establishments.

Occupational Outlook Handbook, 1986-87 Edition. Bulletin 2250, 523 pp., $20 paper cover (GPO Stock No. 029-001-02863-6); $23 cloth cover (GPO Stock No. 029-001-02864-4). An encyclopedia of careers covering more than 200 occupations. For each occupation, information is included on what the work is like, 1984 employment, educational and training requirements, advancement possibilities, job prospects through the mid-1990's, earnings, related occupations, and where to find additional information.

Area Wage Surveys

These bulletins cover office, professional, technical, maintenance, custodial, and material movement jobs in major metropolitan areas. The annual series of 70 is available by subscription for $102 per year. Individual area bulletins are also available separately.

St. Louis, Missouri—Illinois, Metropolitan Area, March 1986. Bulletin 3035-10, 38 pp., $2.25 (GPO Stock No. 829-001-00082-9).

San Francisco—Oakland, California, Metropolitan Area, March 1986. Bulletin 3035-12, 38 pp., $2.25 (GPO Stock No. 829-001-00084-5).

San Jose, California, Metropolitan Area, March 1986. Bulletin 3035-11, 34 pp., $2 (GPO Stock No. 829-001-00083-7).

Periodicals

CPI Detailed Report. Each issue provides a comprehensive report on price movements for the month, plus statistical tables, charts, and technical notes. $4 ($25 per year). May issue includes a reconcilation of two measures of consumer price change for the fourth quarter of 1985.

Current Wage Developments. Each issue includes selected wage and benefit changes, work stoppages, and statistics on compensation changes. $2 ($21 per year). May issue features Employment Cost Index historical tables; major collective bargaining settlements in private industry, first 3 months of 1986; and State and local government collective bargaining settlements in 1985.

Employment and Earnings. Each issue covers employment and unemployment developments in the month plus regular statistical tables on national, State, and area employment, hours, and earnings. $4.50 ($31 per year). May issue features 1985 annual averages for States and areas.

Occupational Outlook Quarterly. Each issue helps people planning careers, guidance counselors, and others keep informed of changing career opportunities. $3 ($11 per year). Spring issue features articles on the job outlook in brief, new projections to 1995, and the occupation of nurse-midwife.

Producer Price Indexes. Each issue includes a comprehensive report on price movements for the month, plus regular tables and technical notes. $4.25 ($29 per year).

U.S. Department of State Indexes of Living Costs Abroad, Quarters Allowances, and Hardship Differentials, April 1986. Tabulations computed quarterly by the Department of State for use in establishing allowances to compensate American civilian government employees for costs and hardships related to assignments abroad. The information is also used by many business firms and private organizations to assist in establishing private compensation systems. $2.75 ($10 per year).

IN THE MAZE
OF ECONOMIC AND SOCIAL STATISTICS,
do you sometimes feel like Stanley hunting for Livingstone?

If so, your search for a single source of reliable and comprehensive statistics and analysis is over. Subscribe to the MONTHLY LABOR REVIEW, the oldest government journal providing up-to-date information on economic and social statistics.

PUBLISHED CONTINUOUSLY SINCE 1915, the REVIEW provides a 40-page section of current statistics covering employment and unemployment; wages, and strike activity; worker and capital productivity; unit labor costs and output; consumer, industrial, and international prices; economic growth; and related topics. Each month, the REVIEW also contains articles and informative reports. Some recent titles are:

- Job Training Partnership Act
- Older workers in the labor market
- Japan's low unemployment
- Employee-owned firms
- The labor force in 1995
- Multifactor productivity
- Import prices for petroleum
- The employment cost index
- Work injuries from falls
- Youth joblessness
- Men's and women's earnings
- Occupational winners and losers
- Black workers' gains
- Shortage of machinists?
- Price inflation remains low
- Employment in energy industries
- Collective bargaining
- Fatal injuries

MONTHLY LABOR REVIEW

AUGUST 1986
VOLUME 109, NUMBER 8

Henry Lowenstern, Editor-in-Chief
Robert W. Fisher, Executive Editor

Susan E. Shank 3 **Employment up, unemployment stable during 1986 first half**
Moderate job growth continued, but only in the service sector and in construction; the jobless rate remained unchanged, as employment gains matched labor force growth

Steven E. Haugen 9 **The employment expansion in retail trade, 1973-85**
Strong employment gains in the industry can be mostly attributed to exceptional growth in eating and drinking places and food stores; more than 1 worker in 3 is a part-timer

Anne Kahl, Donald E. Clark 17 **Employment in health services: long-term trends and projections**
Demand for health services is expected to grow, but job prospects to 1995 are uncertain because of changes that will affect both the financing and delivery of health care

Eileen Appelbaum, Cherlyn S. Granrose 37 **Hospital employment under revised medicare payment schedules**
A case study of the effect of medicare payments based on Diagnosis Related Groups suggests that cost cutting by hospitals will result in smaller but higher skilled staffs

Labor Month In Review

CHANGING DEMOGRAPHICS. A subcommittee of the Congressional Joint Economic Committee conducted hearings in late July on the likely social and economic effects of projected population shifts. Some highlights:

Rep. James H. Scheuer of New York, subcommittee chairman: Four problem areas already are apparent: First is the aging of the population, as women have fewer children, people live longer, and the baby-boom generation grows older. This development will cause major changes in the labor market, in the nature of retirement, in social security, and in the health care system.

Second, we will see big changes in the labor force. The baby boomers born during the 1950's and 1960's are just now entering their prime working years and are swelling demand for good, well-paid jobs. As they approach retirement, there are many fewer young people coming behind to take their places. Thus, the economy is going to have to adjust from an abundance of workers to the possibility of a real shortage.

Third, children will be a declining fraction of the population. Already children make up the majority of Americans in poverty. We are going to have to protect the needs of our children even as we struggle to meet the needs of other population groups, particularly the very old.

Fourth, blacks and other minorities will make up an increasing share of the population. These groups bear a disproportionate share of poverty and unemployment. One of the major challenges facing the public and private sectors is to provide education and job training to these groups.

William E. Brock, Secretary of Labor, pointed to some positive implications of this demographic picture: A slower rate of labor force growth suggests tighter labor markets, which should foster the employment of youth, minorities, women, and the handicapped and a narrowing of occupational and earnings gaps. And a more mature work force implies greater experience, stability, reliability, and productivity.

We have the opportunity to take advantage of projected developments and deal meaningfully with some of the more significant problems our society now faces. But, we must be bold and creative if we are to meet this challenge, specifically by promoting dynamism, flexibility, and adaptability in the economy and labor force.

Janet L. Norwood, Commissioner of Labor Statistics, cited the demonstrated ability of the economy to accommodate large influxes of workers—specifically, women and baby-boom cohorts—although minority groups remain at a severe disadvantage.

The challenge is to make the jobs the economy generates in coming years accommodate the emerging labor force. On the one hand, projected strong growth in highly skilled professional, managerial, and technical occupations will make it easier for the growing proportion of college educated workers to fulfill their job expectations. On the other hand, the shift away from factory operative and laborer occupations may make it more difficult for persons with less education to find jobs.

John G. Keane, director of the Census Bureau, addressed the implications of an aging society: Tomorrow's elderly will be very different from today's in their ability to function effectively in old age. For example, the relatively high educational attainment of the baby-boom generation bodes well for their lifetime economic status. Another indication that the retirement experience will be quite different in the future is based on changes in occupational patterns. Tomorrow's elderly women, for example, will be much more likely to have been in occupations covered by social security and other pension plans, and thus should be in better financial shape than their grandmothers are today.

Roger D. Semerad, Assistant Secretary of Labor for Employment and Training, examined the public policy implications of the population trends through the year 2000, emphasizing the importance of looking ahead to anticipate potential problems rather than merely reacting to the pressure of immediate concerns. Among the more important considerations: ensuring that individuals achieve minimum levels of educational competency; providing quality, education-oriented child care for two-earner families and single parents; orienting workers to a process of lifelong learning and repeated retraining for new and restructured jobs, and involving employers in the reeducation process; assisting workers in adjusting to occupational dislocation; encouraging more cooperative labor-management relations; and developing alternatives to retirement, including nontraditional work schedules and part-time jobs, for older workers. □

Employment up, unemployment stable in the first half of 1986

Moderate job growth continued, but only in the service-producing sector and in construction; the level and rate of unemployment were about unchanged, as employment increases matched labor force expansion

SUSAN E. SHANK

Employment rose at a steady, though unspectacular, pace in the first 6 months of 1986. However, as the economy moved into the fourth year of recovery following the 1981–82 recession, the number of unemployed persons and the unemployment rate were little changed. Civilian employment increases slowed during 1985 and the first half of 1986 from the very robust gains evident in the 2 years immediately after the recession trough. Similarly, the civilian jobless rate, which had dropped sharply during the first 2 years of the recovery, declined only moderately in 1985 and then leveled off at about 7 percent in early 1986.

Job gains during the first half of 1986 took place entirely in the service-producing sector and construction. In contrast, manufacturing employment declined, and the number of mining jobs dropped precipitously—due mainly to the steep fall in oil prices and the consequent layoffs in oil and gas extraction. Most of these developments represented a continuation of the patterns evident during 1985 and reflected both the long-term trend toward the service-producing sector and cyclical developments. The weakness in the goods-producing sector has been especially pronounced in the 1980's, as employment has declined in absolute numbers, augmenting the longer-term decline in relative terms. This sector failed to regain all the jobs lost during the 1980–82 recessions, and its second quarter 1986 employment level (25 million) was about 1.7 million below the July 1979 all-time high.[1]

This article summarizes labor market developments in the first half of 1986 and compares them to earlier periods in the current economic expansion, as well as to long-term trends. The data are from two sources: household interviews and employer reports.[2] Changes during the first half of 1986 refer to movements in seasonally adjusted data from the fourth quarter of 1985 to the second quarter of 1986. References to the last 3½ years cover the period from fourth quarter 1982 to second quarter 1986, and the last 1½ years pertain to 1985 and the first half of 1986.

Employment

Only three of the previous seven economic expansions in the post-World War II period lasted as long as the current one (43 months as of June 1986). The growth rate for civilian employment in the first 3½ years of this expansion was 10 percent, substantially more than the increases during comparable periods after the 1948–49 and 1960–61 recessions, but less than the nearly 13-percent rise following the 1973–75 recession. The robust employment increase in the late 1970's was unusual, because it accelerated in the third and fourth years after the recession. The more typical pattern has been for employment to rebound sharply in the first 1½ to 2 years following a recession trough and then to show moderate growth in subsequent quarters.[3]

The current expansion adhered to the usual pattern of a strong initial rebound followed by slower but steady job growth. In the first half of 1986, the number of employed persons rose by about 900,000 (after allowance for the revisions introduced into the household survey in January 1986),[4] proportionately less than the gains posted earlier in the recovery. At 109.2 million in the second quarter of 1986, civilian employment had expanded by just about

---

Susan E. Shank is an economist in the Division of Employment and Unemployment Analysis, Office of Employment and Unemployment Statistics, Bureau of Labor Statistics.

10 million from the recession trough in the fourth quarter of 1982—with 7 million of the increase occurring in the first 2 years of the recovery and about 3 million coming in the last 1½ years.

Age and sex. Virtually all of the employment increase during the first 6 months of 1986, as well as throughout the current expansion, has been among adults. (See table 1.) Over the 3½ years since the end of the recession, employment rose by about 5 million each for adult men and adult women, while teenage employment was essentially flat. (However, the teenage employment-population ratio rose in the recovery, offsetting declines in their population.) During the first 2 years of recovery, employment gains for men outpaced those for women, as male employment rebounded strongly from the very sharp job cutbacks experienced during the recession. However, in the past 1½ years, the employment increase for women exceeded that for men (2.1 versus 1.2 million).

Occupation. Consistent with overall movements, employment increases for most major occupational groups slowed in 1985 and 1986. Moreover, the composition of the job movements by occupation changed markedly.[5] Nonfarm manual occupations registered very strong gains in the early phase of the economic rebound—7.7 percent for skilled workers and 5.6 percent for semi- and low-skilled workers. The following tabulation shows the percent change in employment for major occupations based on averages for the first 6 months of 1983–86:

	1983–84	*1984–85*	*1985–86*
All occupations	4.9	2.3	2.2
Managerial and professional	5.6	3.7	2.5
Technical, sales, and administrative	4.3	2.6	3.0
Service	3.8	1.7	2.0
Precision production, craft, and repair	7.7	2.8	.2
Operators, fabricators, and laborers	5.6	.3	2.3
Farming, forestry, and fishing	−3.1	−1.1	−1.7

From 1984 to 1985, the expansion was greatest for office workers, especially highly educated managerial and professional workers, while growth slowed for precision production, craft, and repair workers and almost halted for operatives, fabricators, and laborers.

Between 1985 and 1986, office occupations—particularly technical, sales, and administrative support positions—continued to register the largest increases. The small rise for skilled manual workers took place entirely in the construction trades. Similarly, the employment gain among operators, fabricators, and laborers was led by an extremely large increase for construction laborers. In contrast, the number of machine operators, assemblers, and inspectors (almost all of whom are employed in manufacturing) edged up only slightly. The service occupations have experienced only moderate growth throughout the last 3 years, while farming, forestry, and fishing jobs have declined.

Industrial developments

The number of employees on nonagricultural payrolls averaged nearly 100 million in the second quarter of 1986. In the 3½ years since the recession trough, payroll employment has increased by about 11.0 million, with 7.3 million of the gain coming in the first 2 years of recovery and just under 4 million taking place in the last 1½ years. (See table 2.) The moderation in the pace of job growth since late 1984 occurred entirely in the goods-producing sector. The following tabulation shows the change (in millions) in nonfarm jobs in service- and goods-producing industries for selected periods:

	Total	*Service-producing*	*Goods-producing*
Nov. 1982 to May 1986	11.2	9.2	2.0
Nov. 1982 to Nov. 1984	7.3	5.3	2.0
Nov. 1984 to May 1986	3.9	3.9	.0

As shown, goods-producing employment rebounded strongly in the 2 years immediately following the recession, but then showed no net gain in the subsequent 18 months. In contrast, service-producing employment grew robustly, and at a similar rate per month, in both periods.

Service-producing industries. Throughout the current expansion, the largest absolute job gains have been in services and retail trade, although finance, insurance, and real estate also posted substantial increases. Job growth in each of these three industry divisions ranged from 17 to 20 percent over the 3½-year period of recovery, compared with less than 9 percent in the goods-producing sector. During 1985 and the first half of 1986, most service-producing industries continued to record large increases. Services (up 1.7 million) and retail trade (950,000) led the way, followed by government (550,000) and finance, insurance, and real estate (475,000).

Within the services division, business services has experienced phenomenal job growth over the last decade, especially among those firms that provide computer and data processing services and temporary help.[6] Since the recession trough, business services employment has jumped by 1.5 million or 45 percent, with 600,000 of the increase occurring in the past 1½ years. Health services also continued its long-term job growth. Engineering and architectural services, as well as accounting, auditing, and bookkeeping, are two other industries that have registered large job increases over the 1985–86 period.

Retail trade employment continued to advance, but at a slower pace than in 1983 and 1984. Three industries—eating and drinking places, automotive dealers and service stations, and food stores—have accounted for almost all the job growth since late 1984. In contrast, employment in general merchandise or department stores has been about unchanged over the last 1½ years, following a healthy pick-up in the first 2 years of recovery.

Finance, insurance, and real estate, while much smaller than retail trade or services, has also grown at a very brisk pace throughout the current expansion. Moreover, the rate of job growth in this division has accelerated in the last 1½ years, compared with 1983 and 1984. Much of the recent strength has been in finance, reflecting greater activity among mortgage lenders in response to increased demand for new and refinanced home loans at lower interest rates.

Goods-producing industries. Employment trends within the goods-producing sector differed dramatically during the first half of 1986. Construction employment continued to advance strongly, but mining jobs dropped off sharply, and manufacturing employment edged down.

Construction employment has jumped by 1.1 million, or 30 percent, during the current economic expansion—the

largest growth rate for any major industry group. What is more, this expansion was just as robust during the 1985–86 period, when the number of construction jobs rose by about 500,000. Much of the recent strength was related to the upsurge in housing starts in the wake of sharply lower mortgage interest rates. In the initial stage of the recovery, both housing starts and the value of residential construction put in place rebounded sharply, but during 1984 they had leveled off.[7] Also, housing starts, at 1.7 to 1.8 million per year in the 1983–85 period, were below earlier highs of more than 2 million units per year.

Much of the underlying strength in construction in 1984, 1985, and early 1986 has been in private nonresidential building—especially structures for use by service-producing firms.[8] Between 1983 and 1985, the annual value of construction put in place rose by 76 percent for commercial structures other than office buildings. This category includes shopping malls, department stores, warehouses, banks, gas stations, and other buildings intended for use by trade and service businesses. Office building construction also grew substantially between 1983 and 1985 (by about 40 percent), but industrial construction rose by only 12 percent, reflecting the weakness in manufacturing. The value of all private nonresidential buildings increased by a healthy 35 percent between 1983 and 1985, while residential construction rose by 15 percent.

The number of mining jobs fell by approximately 130,000, or 15 percent, in the first 6 months of 1986, after trending downward more gradually since early 1982. Most of the drop took place in oil and gas extraction, which was adversely impacted by the worldwide oil glut and the subsequent collapse of oil prices. At $15 a barrel in May 1986, the price of oil had dropped about 40 percent from the first of the year, and many marginal wells had been shut down. Between December 1985 and June 1986, the oil and gas industry lost 1 of 5 of its jobs.

Manufacturing employment edged down from 19.3 million in early 1986 to 19.2 million in the second quarter, and was considerably below its peak of 21.2 million reached in July of 1979. From that record high to the recession trough in 1982, factory employment fell by 3.1 million; during the first 2 years of recovery, it regained almost half of the jobs lost, but has shown no sustained growth since late 1984. In fact, the number of factory jobs declined during most of 1985 before leveling off in the fourth quarter. In the first half, small job losses occurred in primary metals, machinery, and motor vehicles, as well as in leather. However, small gains in lumber and wood products and stone, clay,

and glass products—related to the construction boom—and in food and printing partially offset the declines.

Unemployment

The number of unemployed persons and the civilian unemployment rate both showed little change during the first half of 1986.[9] However, it is not unusual for the unemployment rate to plateau or even increase slightly following a sharp drop in the first 4 to 6 quarters after a recession. Chart 1 clearly shows this pattern in the four postwar expansions that have lasted as long as 3½ years. In the first year and a half of the current recovery, the civilian jobless rate dropped from 10.7 to 7.3 percent; it then remained at that level for a full year before edging down to 7.0 percent at the end of 1985.

Age and sex. The recent stability in overall unemployment has also been evident for most major worker groups. The 6.2-percent jobless rate for men in the second quarter of 1986 and the 6.4-percent rate for women were little changed from the rates posted in late 1985, but both were at their lowest sustained levels since early 1980. However, the rate for teenagers, at 19.2 percent in the second quarter, was slightly above the rate in evidence during most of 1985.

Although recent jobless rates for most worker groups were at or near their lowest levels in 6 years, they remained substantially above the lows recorded in 1979. The difference is most notable for adult men, who were particularly hard hit by the back-to-back recessions of 1980 and 1981–82. The jobless rate for men jumped from 4 percent in mid-1979 to a recession high of nearly 10 percent. Despite marked improvement in the subsequent 3½ years, the second quarter 1986 unemployment rate for men was half again as high as their rate 7 years earlier. The following tabulation shows unemployment rates for men, women, and teenagers, in selected quarters:

	1979–II	*1982–IV*	*1986–II*
Total, 16 years and over	5.9	10.6	7.2
Men	4.0	9.9	6.2
Women	5.7	9.0	6.4
Teenagers	16.0	23.9	19.2

The impact of the two recessions in the early 1980's was much less marked for women and teenagers. By the second quarter of 1986, jobless rates for both for these groups had dropped back to only slightly above their 1979 levels.

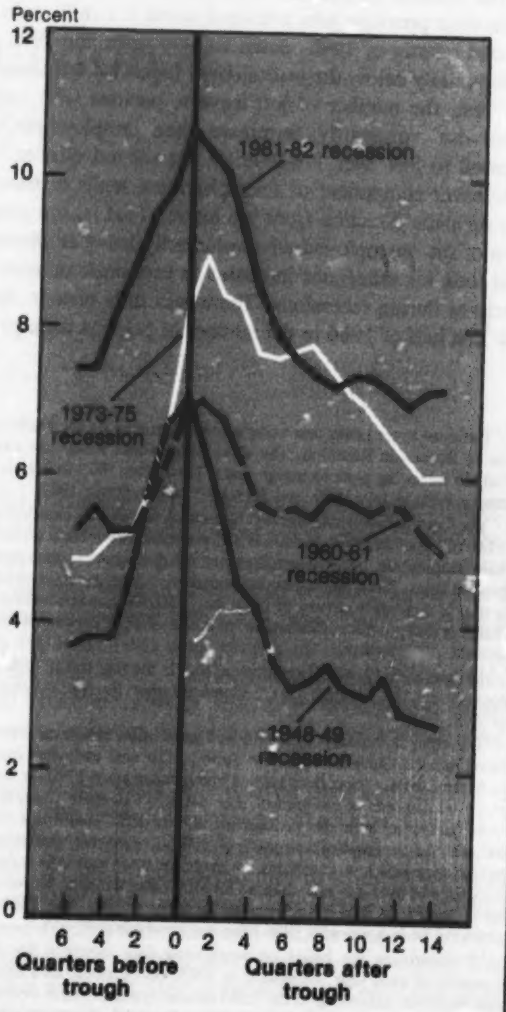
Race and ethnic origin. The unemployment rate for black workers, at 14.9 percent in the second quarter, was about 2½ times the 6.2-percent rate for whites, while the rate for persons of Hispanic origin—at 10.7 percent—remained in an intermediate position. Jobless rates for all three groups showed little change from late 1985 to mid-1986.

However, unemployment rates for the various race-ethnic groups displayed slightly different patterns during the 1979–86 period. The already high black rate did not rise quite as much relatively as the white and Hispanic rates (which nearly doubled) during the 1980 and 1981–82 recessions. The following tabulation shows unemployment rates for whites, blacks, and Hispanics, selected quarterly averages:

	1979–II	*1982–IV*	*1986–II*
Whites	4.9	9.5	6.2
Blacks	12.5	20.4	14.9
Hispanics	8.2	15.3	10.7

Similarly, during the last 3½ years of expansion, the jobless rate for blacks did not fall proportionately as much as did

Chart 1. Cyclical behavior of civilian unemployment rate in four postwar expansions lasting as long as 3½ years



those for whites or Hispanics. Although there have been considerable drops in unemployment since the recession trough, jobless rates for whites, blacks, and Hispanics in mid-1986 were all about one-fourth above their 1979 lows.

Duration and reason. Although the number of unemployed persons held about steady in the first half of 1986, there were shifts in some key categories. Long-term unemployment (15 weeks or more) dipped to 26 percent of total joblessness in the second quarter of 1986, its lowest proportion since mid-1980. Most of the decrease occurred among persons who had been jobless for more than 6 months. Their proportion of total unemployment declined to about 14 percent in the second quarter from $15\frac{1}{2}$ percent in late 1985. The decrease in long-term joblessness was reflected in a lower mean duration of unemployment—14.6 weeks in the second quarter of 1986, compared with about 15.5 weeks in the last 3 quarters of 1985.

The number of persons unemployed because of layoff from their previous jobs averaged about 1.1 million in the second quarter of 1986, down slightly from late 1985 and substantially below the recessionary high of 2.4 million. In contrast, the number of job leavers, persons who quit or otherwise voluntarily terminate their employment, increased to just over 1 million in the second quarter. The job-leaver component of unemployment tends to move in the opposite direction from job losers. That is, the proportion of the unemployed who voluntarily leave employment and look for other jobs increases in economic upturns and declines during recessions. There was little change during the first half of 1986 in the number of persons unemployed because they were entering or reentering the labor force, or in the number of job losers who were not on layoff.

Discouraged workers

In the first half of 1986, there were approximately 1.1 million discouraged workers—persons who want to work but are not actively looking for jobs because they believe that they can not find one. The number was down slightly from the levels that had prevailed in the previous $1\frac{1}{2}$ years. The recent decrease was evident both among persons who cite job market factors as the reason for their discouragement and among those citing personal factors. The decline was concentrated among men and whites—two groups that are underrepresented among discouraged workers. By mid-1986, men, who made up 55 percent of the civilian labor force, accounted for only 35 percent of discouraged workers; whites constituted 86 percent of the labor force, but only 66 percent of the discouraged.

THE MODERATE PACE of economic expansion evident during 1985 continued into the first half of 1986. Employment increases just about matched labor force expansion—leaving both the level and rate of unemployment about unchanged. All of the job growth in the past $1\frac{1}{2}$ years has taken place in the service-producing sector—especially the services and retail trade industries—and in construction. Manufacturing employment has edged down since the end of 1985. Mining employment fell precipitously during the first half of 1986, as lower oil prices resulted in sharp reductions in the number of jobs in oil and gas extraction. □

FOOTNOTES

[1] Business cycle peaks and troughs are designated by the National Bureau of Economic Research. The three most recent recessions extended from the following peak-to-trough dates: November 1973 to March 1975, January 1980 to July 1980, and July 1981 to November 1982.

[2] The Current Population Survey (household survey) is a monthly sample survey of about 59,500 households and provides information on the labor force, employment, and unemployment by demographic and economic characteristics. The Current Employment Statistics program (establishment survey) is a monthly survey of more than 250,000 nonagricultural establishments and provides information on the number of persons on business payrolls.

[3] See Susan E. Shank, "Employment rose in the first half of 1985, as the recovery entered its third year," *Monthly Labor Review*, August 1985, pp. 3–8.

[4] Effective in January 1986, revised population estimates were introduced into the Current Population Survey. The new estimates include an explicit allowance for undocumented immigration since 1980, as well as an improved estimate of emigration. The net effect of these changes was to cause jumps in both the civilian population and labor force of about 400,000 and an employment jump of 350,000 (between December 1985 and January 1986). Adjustments are made for these breaks in series in the discussion of over-the-year changes for all civilian workers. However, with the exception of data for persons of Hispanic origin, data shown in the tables for periods prior to 1986 have *not* been adjusted.

[5] Comparisons are based on unadjusted data averaged for the first 6 months of each year. Beginning in 1983, occupational data were coded and published according to the 1980 census system, which evolved from the Standard Occupational Classification. Seasonal adjustment will not be possible until at least 5 years of data are available on the new classification system. For further information, see "Revisions in the Current Population Survey Beginning in January 1983," *Employment and Earnings*, February 1983, pp. 7–15.

[6] See the following articles in the April 1986 *Monthly Labor Review:* Wayne J. Howe, "The business services industry sets pace in employment growth," pp. 29–36; and Max L. Carey and Kim L. Hazelbaker, "Employment growth in the temporary help industry," pp. 37–44.

[7] See U.S. Bureau of the Census, *Construction Reports-Value of New Construction Put in Place: May 1985*, C-30-85-5, and later monthly news releases. All references to value of construction are in constant (1977) dollars.

[8] Employment data for construction are classified differently from data on the value of construction put in place. The latter estimates are based on the type of construction or the final use of the project. Employment data are classified in two ways: first, based on the type of builder (general or special trades contractors) and second, for the general contractors on whether they construct buildings (of all types) or other projects. The most rapid employment growth in recent years has been among special trades contractors, for example, firms specializing in plumbing, painting, electrical work, or carpentry. These contractors work on all types of construction—residential and nonresidential, private and public.

[9] On a monthly basis, the unemployment rate declined from 6.9 to 6.7 percent in January 1986, but increased in February to 7.3 percent. Both of these movements appear to have been exaggerated owing to several factors, including coding errors on a question that was reworded slightly in January and exceptionally mild weather in January that was followed by stormy weather in February.

The employment expansion in retail trade, 1973–85

Strong employment gains in the industry can be attributed mostly to exceptional growth in eating and drinking places and food stores; part-time positions accounted for much of the overall growth

STEVEN E. HAUGEN

One of the largest and fastest growing industries in the United States, in terms of employment, is retail trade. Nearly 17.4 million persons were employed in this field in 1985, or more than 1 of every 6 nonagricultural wage and salary workers. From 1973 to 1985, retail trade employment expanded by 5 million, accounting for a fourth of the total nonagricultural employment increase over the period. Only services and manufacturing employed a larger number of workers, and only services; finance, insurance, and real estate; and mining exhibited a higher rate of employment growth over the 12-year period. Although growth in retail trade employment was pervasive, a closer inspection reveals that most of the increase can be attributed to very sharp expansion in two key industries within the retail trade division—eating and drinking places, and food stores.

This article discusses employment trends in retail trade as well as in key industry groups since 1973. In addition, it explores the changing demographic, occupational, and earnings characteristics of retail trade workers, as well as the incidence of self-employment in the industry. Data for the years 1973 and 1985 were chosen for comparison, because they are indicative of periods characterized by relatively robust economic activity and, more importantly, because they each represent the third year of recovery following a recession.[1]

Data for this study were derived from both the Current Employment Statistics survey and the Current Population Survey.[2] The Current Employment Statistics survey is a monthly sample of the payroll records from 250,000 business establishments nationwide and is widely regarded as the most detailed and statistically reliable source of information on industry employment, hours, and earnings. Data from this survey are used in the analysis of employment and earnings trends among wage and salary workers in retail

trade industries over time. However, because the payroll survey does not provide information on the demographic or occupational characteristics of workers, or on self-employed and unpaid family workers in the industry, data on these subjects were derived from the Current Population Survey, a monthly sample survey of 59,500 households nationwide.

What is retail trade?

The role of retail trade industries in a market-based economy is obvious: to serve as "middlemen" between those who supply goods and those who purchase the goods for final consumption. More formally, the retail trade division, as defined in the 1972 *Standard Industrial Classification Manual,* includes ". . .establishments engaged in selling merchandise for personal or household consumption, and rendering services incidental to the sale of the goods." These firms are classified into eight major component industries, including general merchandise stores, food stores, automotive dealers and gasoline service stations, apparel and accessory stores, and eating and drinking places.[3] Altogether, there were about 2 million retail establishments in 1982.[4] Clearly, retail industries are the major conduits for the distribution of goods from producer to consumer. As such, they should be distinguished from their wholesale trade counterparts, which employ roughly one-third as many workers basically in the sale of goods to retailers or to industrial or commercial users.

Retail trade, by nature, is highly labor intensive, and by and large it is the retail worker who usually plays the preeminent role in the transaction between buyer and seller. Although there have been recent developments in the way retailers conduct business that are lessening the dependence upon workers for certain tasks, such as the extensive use of computerized gasoline pumps to serve customers, there are many services provided by the industry for which it has been exceedingly difficult to substitute capital for labor. Whether through providing information and assistance to the customer in the selection of the product, ringing up the sale, or in delivering the product, the retail worker is an intrinsic and seemingly irreplaceable "factor of production" in the industry. Therefore, just as consumer demand for all kinds of merchandise has increased over time, retail employment has expanded to handle the larger number of transactions between producer and consumer.

Overall growth

Employment in retail trade expanded by 5.0 million between 1973 and 1985, an increase of about 41 percent. By comparison, employment in all nonagricultural industries increased by about 27 percent. Relatively stronger employment growth in retail trade over the period reflects not only increases during business expansions that were either proportionately equal to or greater than those for all industries, but also more resilience to employment declines during each of the three recessions that occurred during the 12-year period under study. The following tabulation shows seasonally adjusted percent changes in employment during selected business cycle expansions and contractions. (As of March 1986, the economy was in the 40th month of business recovery since the recession trough in November 1982.)

Business cycles	*All nonagricultural industries*	*Retail trade*
Expansions:		
March 1975–January 1980	18.8	20.6
July 1980–July 1981	2.0	1.9
November 1982–March 1986	12.2	17.5
Contractions:		
November 1973–March 1975	−1.8	0
January 1980–July 1980	−1.2	−1.0
July 1981–November 1982	−3.0	−0.4

It may seem somewhat surprising that employment in retail trade was not only far less affected by cyclical downturns than that in all nonagricultural industries, but also that it barely declined at all in the two longer recessions of the 1973–85 period. Logically, when consumer demand wanes, employment in retail trade would be expected to decline as fewer workers are needed to handle the smaller volume of sales. Indeed, although overall employment in the retail division remained relatively unchanged during the three contractions, a closer look reveals that there were substantial differences in the response to cyclical and other developments by individual retail industries.

Employment growth by industry

For the purposes of this analysis, the eight major industry groups within the retail trade division can be broken down into three groups: 1) "slow" growth industries—those which grew only slightly during expansions and experienced deep employment declines as a result of recessions, resulting in little growth over the 1973–85 period, 2) "medium" growth industries—those which exhibited marked employment growth over the period, growing during recoveries and suffering only moderate declines during recessions, and 3) "strong" growth industries—those which grew very sharply during expansions and continued to grow during contractions, thereby establishing a pattern of extraordinary employment growth over the entire period. (See table 1.)

Slow growth industries. The general merchandise stores and automotive dealers and gasoline service stations industry groups exhibited the slowest rate of growth among the retail industries over the period, each expanding by less than 7 percent over the entire 12 years. The general merchandise stores industry, the third largest retail employer in 1985, is basically comprised of department stores and similar establishments which sell a wide variety of products. The industry had been the second largest in 1973 when it employed some 2.2 million workers. However, relatively weak employment growth since that time, in part reflecting sharp and protracted employment declines as a result of business cycle contractions, substantially eroded its share of retail employment. By 1985, the industry employed 2.3 million workers. Automotive dealers and service stations, at 1.9 million in 1985, were only 115,000 above the 1973 level. Like general merchandise stores, this industry was severely affected by cyclical downturns (which is not surprising, given the industry's close attachment to the very cyclically sensitive automobile manufacturing industry). In addition, the gasoline crises of 1973 and 1979 had a deleterious impact on automotive dealers and gasoline service stations. Resultant losses limited overall employment growth over the 1973–85 period.

Medium growth industries. The building materials and garden supplies, apparel and accessories, furniture and home furnishings, and miscellaneous retail industries registered substantially greater employment growth than the first group of industries over the period. Among these four industries, growth was proportionately the smallest for the building materials and garden supplies industry. Comprised of all stores which sell primarily lumber, hardware, and other building supplies, this industry grew by 28 percent, employing a total of 685,000 persons by 1985. Slightly stronger employment growth occurred within apparel and accessories, as clothing stores and related establishments employed about 1 million persons in 1985, or 31 percent more than in 1973. The furniture and home furnishings industry exhibited fairly sharp growth, expanding by 38 percent to an employment level of 735,000 in 1985. Like the "slow" growth group, though to a lesser degree, all three of these industries suffered significant employment losses as a result of the recessions which occurred over the 1973–85 period. The last member of this "medium" growth group, miscellaneous retail, added 640,000 workers over the period, reaching a level of 2.2 million workers. This represents an expansion of 41 percent. Miscellaneous retail includes all retail establishments that cannot be classified in the seven other industries, such as drugstores, bookstores, and mail order houses.

Strong growth industries. Food stores and eating and drinking places comprised the "strong" growth group. The food stores industry, which includes all businesses which primarily sell food for home preparation, grew rapidly over the period and by 1985 was the second largest industry within retail trade. This industry is comprised of groceries, bakeries, various produce markets, and similar establishments. There were 2.8 million workers employed in the food stores industry in 1985, up roughly 925,000 from the 1973 level, representing an increase of 50 percent.

The eating and drinking places industry, which remained the largest industry in the division throughout the period, registered the highest employment growth rate since 1973 among the eight retail industries (87 percent). Composed of restaurants of all types, including cafeterias, fast food restaurants, and sit-down eating places, as well as a full range of establishments engaged in the retail sale of beverages for on-site consumption, the industry employed 5.7 million persons in 1985, up 2.7 million since 1973. Thus, this industry alone accounted for half of total employment growth in retail trade over the period.

Eating and drinking places and food stores industries together employed 8.5 million persons in 1985 (about half of all retail workers), and accounted for 71 percent of employment growth in retail trade since 1973. (See chart 1.) Not only did these industries grow at a much faster pace than the rest of retail trade during expansions, but employment increases in these industries during recessions were sufficient to largely offset declines that occurred in the rest of the retail industries.[5] The following tabulation shows the changes in employment in the eating and drinking places and food stores industries and all other retail industries during selected business cycle expansions and contractions

Table 1. Number of employees in the retail trade industry by major division, 1973–85 annual averages
[In thousands]

Year	Total nonagricultural employees	Total retail trade	Building materials and garden supplies	General merchandise stores	Food stores	Automotive dealers and service stations	Apparel and accessory stores	Furniture and home furnishings stores	Eating and drinking places	Miscellaneous retail trade
1973	76,790	12,329	535	2,229	1,856	1,778	795	533	3,054	1,551
1974	78,265	12,554	542	2,210	1,948	1,666	811	538	3,231	1,609
1975	76,945	12,645	521	2,113	2,007	1,677	806	517	3,380	1,625

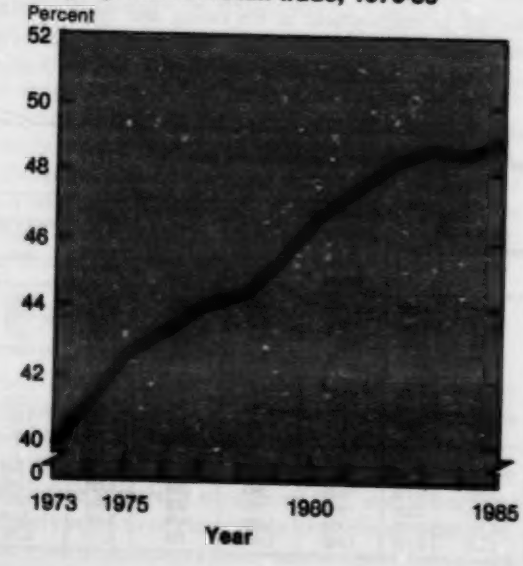
Job growth factors

There are many factors which can be associated with employment growth in retail trade since 1973. Obviously, increasing consumer demand is largely responsible, and to some extent, this simply reflects population growth and the increase in aggregate income over the period. Perhaps more importantly, there are many demographic and socioeconomic developments which have directly and indirectly magnified demand for goods and services in general, including the increased incidence of working women, and thus of two-income families; an increased number of persons who live alone; and a general trend towards increased demand for leisure time. One end product of these changes is the gradual emergence of a more affluent society, in which time has become a scarcer resource.[6] This, in turn, has led to increased customer demand for convenience. Consumers have less time for shopping, and they want to be able to shop whenever time becomes available. As a result, many retail stores have not only increased in size and number, but have expanded their hours of operation as well. Both factors have resulted in the addition of more workers in retail trade, particularly part-timers. Probably the greatest impact of these developments has been in the eating and drinking and food store establishments.

Chart 1. Employment in eating and drinking places and food stores as a percentage of employment in retail trade, 1973-85



It is generally more expensive to eat meals prepared in restaurants than it is to eat at home, and this disparity has widened over time. Consequently, all other things being equal, one would expect to see a cutback in the amount of dollars spent on food away from home. In fact, there has been a change in eating habits. Data from BLS Consumer Expenditure Surveys indicate that between 1972–73 and 1982–83, not only has the proportion of the overall consumer's budget spent on food declined, but that of this total food budget, the proportion spent on food away from home has increased significantly.[7] This preference of eating out to cooking at home can certainly be associated with the increasing desire to conserve time, as it typically takes more time to prepare a meal at home than it does to eat out. As noted previously, there are many groups that have had more constraints placed upon their available time, and many of them find it more convenient to eat out, augmenting demand for the industry.[8]

But if this is the case, then why has demand in the food stores industry increased as well? In addition to the marked population growth over the period, one possible reason for the increase over time is the growing diversification of products offered by grocery stores. To meet the customer's growing demand for convenience, grocery stores have increasingly offered many services and products that once were the province of other industries.[9] These include the installation of delis and salad bars, service centers for check cashing, and other services such as film processing.[10] Ultimately, demand for the industry has increased as people are able to obtain a wider selection of goods with just one stop at a store, thereby saving time.

Technical innovations and productivity

Employment growth in retail trade over the 1973–85 period would probably have been even more dramatic had it not been for the adoption of many labor-saving and management-related innovations which have helped to increase productivity in the sector. For example, the use of computer technology to manage inventories and handle customer billing and accounting has limited the labor resources that were once needed to handle these tasks.[11] In addition, the overall trend towards consumer self-selection of merchandise has limited labor requirements in many industries, such as the proliferation of self-service pumps at gas stations and convenience stores and the self-selection of products in apparel and department stores.

In part reflecting these innovations, productivity in the retail trade division increased at an average annual rate of

1.0 percent from 1973–84, slightly higher than the 0.8 percent recorded for the total business sector.[12] However, there were divergent movements in productivity over the period for many of the detailed retail industries. In fact, among the retail industries for which data are available, there were average annual productivity declines for only two industries, eating and drinking places and food stores. As increased output can be satisfied by either increased productivity or increased input, these two industries were increasingly reliant upon labor to meet the higher output requirements.

Characteristics of retail workers

An understanding of certain characteristics of the retail trade work force helps explain employment patterns and trends in this industry division. Historically, the retail trade work force has differed in many respects from the overall work force. For example, the industry has typically employed a disproportionately large share of part-time workers, women and young persons, sales and service workers, workers who have below average earnings, as well as self-employed and unpaid family workers. While this profile has changed little between 1973 and 1985, there have been important changes in the proportionate representation of these groups.[13]

Part-time workers. Employment growth in retail trade may be somewhat misleading if one does not note the fact that much of the growth reflected large increases in the size of the part-time component. More than 1 of every 3 retail trade workers was employed on a part-time basis in 1985—twice the proportion of total nonagricultural employment. Although the services industry employed a larger number of part-time workers, no other industry had such a large proportion of its work force putting in fewer than 35 hours per week. Part-time employment was even more prevalent in 1985 than it had been 12 years earlier. In fact, about 40 percent of the employment growth in retail trade since 1973 has been among part-time workers; the relative contribution of part-timers to total employment growth for all nonagricultural industries was about one-fourth.[14] (See table 2.) This finding is supported by data from the establishment survey, which show that average weekly hours in the industry have fallen by about 11 percent since 1973, twice the proportional decline in all private nonagricultural industries.

Table 2. Percent distribution of employed wage and salary workers in the retail trade industry by selected characteristics, 1973 and 1985 annual averages

Characteristics	1973		1985	
	Total	Retail trade	Total	Retail trade
Total, 16 years and over	100.0	100.0	100.0	100.0
16 to 19 years	8.7	21.6	6.1	18.5
20 to 24 years	15.0	16.7	13.8	21.4
25 years and over	76.3	61.7	80.0	60.1
Men, 16 years and over	61.1	52.0	54.9	47.6
16 to 19 years	4.8	11.6	3.1	8.8
20 to 24 years	8.3	9.3	7.1	10.2
25 years and over	47.9	31.1	44.6	28.5
Women, 16 years and over	38.9	48.0	45.1	52.4
16 to 19 years	3.9	10.0	3.0	9.7
20 to 24 years	6.7	7.4	6.7	11.2
25 years and over	28.4	30.6	35.4	31.6
Full-time workers[1]	86.1	68.0	83.8	65.3
Men, 16 years and over	56.4	41.1	49.9	36.2
Women, 16 years and over	29.7	26.9	33.9	29.1
Part-time workers[1]	13.9	32.0	16.2	34.7
Men, 16 years and over	4.7	10.9	5.0	11.4
Women, 16 years and over	9.3	21.1	11.2	23.3

[1] Employed persons with a job but not at work and persons at work part time are distributed according to whether they usually work full or part time.

NOTE: Data were obtained from the Current Population (household) Survey and exclude agricultural and private household workers.

There are several reasons part-time employment is so prevalent in retail trade. From the standpoint of the employer, hiring part-time workers is an efficient way to handle changes in the extended hours of operation necessitated by ever-fluctuating consumer demand for retail goods. Consumer demand for many products varies seasonally, monthly, and even daily. As mentioned earlier, the emergence of a "time-scarce" American consumer has exacerbated the variability of peak and non-peak periods of demand. The result is that most retailers must stay open evenings, Saturdays, and, in many cases, even Sundays, to capture as much of this demand as possible. However, because these oscillations in demand are somewhat predictable, the retailer can use part-time labor to meet the demand at any given time.[15]

Just as many retailers have a need for part-time workers, so do many workers have a need for part-time jobs. Part-time schedules are often fairly flexible, allowing the worker time for other activities. This being the case, it is not surprising that women and young workers make up a large portion of the part-time workers in the industry. For example, in 1985, two-thirds of the part-time work force in retail trade were women. For many women, part-time work affords the option of supplementing family income while still allowing time for maintaining a home and child rearing; for youth, part-time work is scheduled around school attendance.

Demographic characteristics of workers. When compared with other industries, retail trade has always had a disproportionately high concentration of women and young workers. Women accounted for just under two-thirds of the employment growth in the industry between 1973 and 1985, boosting their proportion of the retail trade work force to just over one-half. This increase reflects changes occurring in the work force, as women also made up two-thirds of employment growth in all nonagricultural industries over the same period; as a result, the proportion of women in the work force increased from 39 to 45 percent.

The situation is somewhat different for young workers. Despite the general aging of the overall work force, young workers (16 to 24 years of age) commanded an even larger share of retail trade employment in 1985 than in 1973. This was entirely due to very large increases in the number of retail workers 20 to 24 years of age. In fact, about 73 percent of the increase in total industry employment for workers ages 20 to 24 occurred in retail trade. Teenagers accounted for about 1 of every 5 retail workers in 1985, and more than half of all employed teens worked in retail trade. On the whole, about 40 percent of all workers in retail trade were less than 25 years of age in 1985, twice the percentage for the overall work force; the figures in 1973 were 38 and 24 percent, respectively. (See table 2.) There is little variation in the extent to which whites and minorities hold jobs in retail trade. About 17 percent of both white and Hispanic workers were employed in the industry in 1985, compared with about 14 percent of black workers.[16]

There are several likely reasons for the relatively high prevalence of young and female workers in retail trade. Young workers typically have fewer job skills and less training than their older counterparts. In addition, as mentioned earlier, both young and female workers have a relatively high proclivity to work part time. Based on the fact that skill requirements in the industry are generally low, and that part-time work arrangements are often easily accommodated, many young and female workers find positions in the industry very suitable.

Occupation. Sales and service jobs were the most prevalent occupations in retail trade in 1985.[17] About 42 percent of all workers in the industry held sales positions, and about 23 percent were employed in service jobs. Most of those in the latter category worked in eating and drinking places. Combined, these two occupational groups accounted for almost two-thirds of the employed total in retail trade; this compares with about 25 percent of those in all industries. Within retail trade, the most prevalent occupations in the sales and service areas were salesworkers, sales supervisors, cashiers, and food preparation and service workers. (See table 3.)

Table 3. Occupational distribution of employment in the retail trade industry, 1985 annual averages

Occupation	1985	
	Total employed	Retail trade
Total employed	100.0	100.0
Managerial and professional specialty	24.1	9.5
Executive, administrative, and managerial	11.4	7.6
Professional specialty	12.7	1.9
Technical, sales, and administrative support	31.0	50.0
Technicians and related support	3.0	.3
Sales occupations	11.8	41.6
Administrative support, including clerical	16.2	8.1
Service occupations	13.5	23.3
Private household	.9	—
Protective service	1.6	.3
Service, except private household and protective	10.9	23.0
Precision production, craft, and repair	12.4	6.4
Operators, fabricators, and laborers	15.7	10.7
Machine operators, assemblers, and inspectors	7.3	.8
Transportation and material moving occupations	4.2	2.3
Handlers, equipment cleaners, helpers, and laborers	4.1	7.6
Farming, forestry, and fishing	3.2	.1

NOTE: Data were obtained from the Current Population (household) Survey.

Earnings. Pay in the retail trade industry has historically been below average, and the disparity has widened. Weekly earnings in the industry (derived from the Current Employment Statistics survey), at $175 in 1985, were 58 percent of the figure for all private nonagricultural wage and salary workers; this ratio was down from 66 percent in 1973. Within retail trade, weekly earnings ranged from a high of $273 in automotive dealerships and service stations to $112 in eating and drinking places in 1985. (See table 4.)

A study of earnings in the industry is complicated, however, by the many varied pay arrangements. Commissions and tips supplement, to varying degrees, earnings within

Table 4. Average weekly earnings of private nonagricultural production or nonsupervisory workers in the retail trade industry, 1973–85 annual averages

Year	Total private nonagricultural employees	Total retail trade	Building materials and garden supplies	General merchandise stores	Food stores	Automotive dealers and service stations	Apparel and accessory stores	Furniture and home furnishings stores	Eating and drinking places	Miscellaneous retail trade

NOTE: Data were obtained from the Current Employment Statistics (establishment) survey.

several component industries. Earnings received on a commission basis, which are included in the Current Employment Statistics survey, occur in industries with a heavy proportion of salesworkers, and vary according to product sold. Big ticket items, such as automobiles, major appliances, and jewelry offer the best chance for commission-type arrangements. Presumably, tips, which are excluded from the survey, are the most common type of compensation over and above regular pay in eating and drinking places. As a result, the payroll data somewhat understate the average earnings of workers in this industry.

Many jobs in retail trade offer no such supplement to regular wages, and therefore it is useful to look at the earnings of workers paid at an hourly rate. Data from the Current Population Survey indicate that the median hourly earnings for retail trade workers paid at an hourly rate in 1985 were $4.15. About two-thirds of those workers paid at hourly rates made less than $5 an hour. About one-fourth earned the prevailing minimum wage of $3.35 or less—a much larger proportion than in any other industry. In fact, half of all minimum wage and subminimum wage workers were employed in retail trade.[18]

There are several characteristics of the retail trade work force which can be associated with the generally low earnings in the industry division. These include, among others, an occupational structure heavily biased toward sales and service positions, employment disproportionately composed of young workers, and industry operations that are tailored for part-time positions. Because these groups and job characteristics are associated with lower pay in general, it follows that earnings in retail trade would be affected negatively. Indeed, the increasing proportionate sizes of these groups in retail trade over time may be related to the widening earnings gap between the industry and the all-industry average.

Self-employed and unpaid family workers. While wage and salary employment in retail trade grew markedly between 1973 and 1985, the number of self-employed workers in the industry changed very little. As a result, their proportion of total employment declined from 10 to 8 percent over the period. The number of unpaid family workers in the retail industry actually fell over the period, and by 1985, they represented less than 1 percent of the employed total in the sector. Both of these developments suggest a decline in the role of self-owned retail businesses in the industry.

THE RELATIVELY STRONG employment growth in the retail trade division over the 1973–85 period can mostly be attributed to extraordinary growth in eating and drinking places and food stores. Although a few other retail industries exhibited substantial employment growth over the period, several factors, including the increased importance of spare time and convenience to consumers, augmented demand for eating and drinking places and food stores to a much larger extent than that for retail trade in general. BLS projections indicate that employment growth in eating and drinking places and in food stores will continue strongly through 1995, albeit at a slightly slower pace than in the past. This, combined with projected declines in the rate of employment growth among other retail industries, seems to suggest that in contrast to past performance, overall retail trade employment growth over the 1984–95 period will be only slightly stronger than that for all industries.[19] ☐

FOOTNOTES

[1] The business cycle expansion and contraction periods are determined by the National Bureau of Economic Research, a private, nonprofit research organization located in Cambridge, MA.

[2] Because the two sources differ in definition, coverage, methods of collection, and estimating procedures, estimates of employment are not identical. For a detailed comparison of the two surveys, see the "Explanatory Notes" section of the BLS monthly publication, *Employment and Earnings*.

[3] The following industry groups comprise the major "two-digit" retail industries in the sector:

SIC 52—Building materials, hardware, garden supply, and mobile home dealers
SIC 53—General merchandise stores
SIC 54—Food stores
SIC 55—Automotive dealers and gasoline service stations
SIC 56—Apparel and accessory stores
SIC 57—Furniture, home furnishings, and equipment stores
SIC 58—Eating and drinking places
SIC 59—Miscellaneous retail

These groups are further broken down into more detailed three- and four-digit industries. See the U.S. Office of Management and Budget's *Standard Industrial Classification Manual, 1972*, for further information and a more detailed explanation of the codes.

[4] See *1982 Census of Retail Trade* (Bureau of the Census, Nov. 1984), p. 2.

[5] One characteristic common to both of these industries that substantially insulates them from cyclical downturns, and thus the associated employment losses, is that food and related products represent a "need" rather than a "want." Consequently, potential employment declines in these industries are mitigated. However, the fact that employment in these industries actually grew significantly during the three recessions reflects considerable consumer demand for their products.

[12] Data were obtained from both published and unpublished matrices from the BLS Office of Productivity and Technology. The productivity figures represent output per hour of all persons. Average annual productivity rates of change over the 1973–84 period for the total business sector,

retail trade, and available detailed retail industries are:

Total business sector	.8
Retail trade	1.0
SIC 54—Food stores	−.7
SIC 5511—Franchised new car dealers	.8
SIC 5541—Gasoline service stations	3.1
SIC 56—Apparel and accessory stores	3.7
SIC 58—Eating and drinking places	−.7
SIC 5912—Drugstores	1.3

[13] For information on the characteristics of workers in the retail trade industry over the 1968–78 period, see Barbara Cottman Job, "Employment and pay trends in the retail trade industry," *Monthly Labor Review*, March 1980, pp. 40–43.

[14] These data are based on a new definition of part-time employment recently developed by BLS. For a discussion of the new definition, see Thomas Nardone, "Part-time workers: who are they?" *Monthly Labor Review*, February 1986, pp. 13–19.

[15] For information on the demand for part-time labor in retailing, see Roy Thurik and Nico Van Der Wijst, "Part-Time Labor in Retailing," *Journal of Retailing*, Fall 1984, pp. 62–68.

[16] Persons of Hispanic origin are included in both the black and white population groups.

[17] Beginning with data for 1983, occupational data are classified according to the system used in the 1980 census, which was redesigned to reflect the occupational structure of the changing economy. This system is radically different from the 1970 census-based system which was adopted in 1972 and used through 1982. Therefore, data for 1985 are not comparable with pre-1983 estimates, and for this reason, occupational data for 1985 only are discussed in the text. Occupational data used in this report are representative of all workers in the retail trade industry, including the self-employed, private household workers, and unpaid family workers. Although these components are relatively small, it should be noted that these figures differ from the data used in the discussion of part-time, women, and young workers, which represent only nonagricultural wage and salary workers excluding private household workers.

[18] It should be noted, once again, that many of these hourly paid workers receive wages that are supplemented in varying degrees by tips and commissions. Furthermore, the existence of a substantial group of retail workers earning below the minimum wage does not necessarily indicate violations of the Fair Labor Standards Act but in fact may reflect exemptions to the Act, many of which pertain to the retail trade industry. For further information, and a more complete list of full and partial exemptions, see *Report of the Minimum Wage Study Commission*, vol. I, pp. 107–38.

Employment in health services: long-term trends and projections

Demand for health services is expected to grow in response to the increasing number of elderly people; but growth prospects to 1995 for the industry's wage and salary workers are uncertain because of changes in both the financing and delivery of health care

ANNE KAHL AND DONALD E. CLARK

Health care has aptly been described as a system in flux.[1] Throughout much of the post-World War II period, U.S. health policy encouraged expansion of the delivery system and of patients' access to it. There was a perceived need for more physicians and hospitals, and strategies were developed to increase the supply. The number of beds in hospitals and nursing homes rose, and the supply of physicians, nurses, and allied health professionals grew very rapidly. Now that cost control has emerged as a dominant concern, this has changed: evolving methods of payment for health services are based on incentives intended to discourage use of costly resources and to foster price competition. Greater emphasis on providing care in the most cost-effective setting is one of the principal trends reshaping this large and important industry.[2] This article explores the potential impact on demand for health services workers of the sweeping changes in industry structure currently underway.

Health care is still delivered in doctors' and dentists' offices, hospitals, and nursing homes, for the most part, but the structure of the industry is changing as financial incentives for providing (and using) health services are transformed. Health maintenance organizations (HMO's) are flourishing and new organizational entities such as urgent care centers, birthing centers, and hospices are taking hold.

The boundary between financing and delivery of health care is becoming less distinct, and vertically integrated systems of care are emerging as providers affiliate with one another, or with hospitals, HMO's, and insurance companies. Additional changes in organizational structure lie ahead, inasmuch as financing is in ferment. The prospective payment system launched by medicare in October 1983 may be modified as evidence of its impact accumulates and other payers are experimenting with cost containment programs of their own.

Yet even as the delivery system changes, equally dramatic shifts are occurring in the composition of the U.S. population. Americans are growing older, creating a need for suitable health, housing, and social services. Moreover, the segment age 85 and above is recording much faster growth than any other age group in the population. In the decade ahead, the increasing number of elderly people, especially those of very advanced age, is expected to heighten demand for hospital, medical, and surgical care; for long-term care services; and for new services, including geriatric assessment, case management, adult day care, and respite care. The effort to provide adequate and appropriate health care for an aging population within the constraints imposed by cost containment is stimulating innovative approaches to

Anne Kahl is an economist in the Office of Economic Growth and Employment Projections, Bureau of Labor Statistics. Donald E. Clark is an economist formerly in the same office.

program design, organization, and financing. With both the scope and structure of health care services delivery in flux, however, it is very difficult to anticipate the future pattern of health services.

Given the growth and aging of the population, advances in medical technology, and public support for high-quality care, there is little doubt that the health services industry will continue to grow over the 1984–95 period that is the focus of this article. However, there is considerable uncertainty as to how rapid future growth will be, and what the employment implications are likely to be. This article, undertaken in connection with the Bureau of Labor Statistics' expanding coverage of the service sector, illustrates the wide range of possibilities. It sets up a series of alternative scenarios based on qualitative judgments about the possible course of events affecting the health services industry and provides projections of industry and occupational employment consistent with those assumptions.

The Bureau has for several decades developed medium-term projections of the U.S. economy under alternative sets of assumptions. The latest set of 1995 projections is presented in four articles in the November 1985 issue of the *Review*.[3] The low-growth, moderate-growth, and high-growth alternatives presented there for all industries reflect alternative fiscal and monetary assumptions, rates of growth of productivity, unemployment rates, or what may be thought of as macro alternatives. This article explores the prospects for a single industry sector, the health services industry, under micro alternatives outlined in exhibit 1.

No attempt was made to quantify the effects of specific assumptions in exhibit 1; rather, they portray service delivery patterns and interrelationships that might reasonably be expected to generate varying levels of demand for health services. The base case projections presented here were taken directly from the moderate-growth projections for the health services industry, while the low- and high-scenario projections were derived from analytical judgment. Projections tied to all three alternative scenarios thus represent a qualitative assessment of the likely effect on industry output and employment of alternative courses of events in the health services industry.

This analysis pertains to wage and salary workers in the health services industry only. Excluded are self-employed and unpaid family workers, on the one hand, and workers employed outside the health sector, on the other. Examples of health professionals excluded from the analysis are (1) physicians, dentists, podiatrists, chiropractors, pharmacists, nurses, physical therapists, speech pathologists and audiologists, and other practitioners who are self-employed; and (2) nurses, nursing aides, dietitians, dental hygienists, social workers, psychologists, occupational therapists, physicians, dentists, and others employed in schools, prisons, residential care facilities, temporary help agencies, and other industry sectors outside health. These exclusions have different effects on the validity of the analysis, depending on the occupation or industry of interest. Only about 1 physician in 4 is self-employed and, as such, excluded from the scope of this study. However, most chiropractors, and many dentists, podiatrists, and optometrists are self-employed, which diminishes the relevance of this analysis for those occupations. Note, however, that self-employed practitioners generally work in one or another of the health services industry sectors, and are subject to many of the same trends as wage and salary workers in those sectors. Confining the analysis to the health services industry limits the ability to generalize the findings, too. Because of differences in industry distribution, the projections cover virtually all radiologic technologists, for example; about 4 of 5 registered nurses; 3 of 5 occupational therapists; but only about 1 of 5 speech pathologists and audiologists, social workers, or psychologists.

Projection highlights

The health services industry is defined according to the 1972 Standard Industrial Classification (SIC), and includes the following:

SIC	
801	Offices of physicians
802	Offices of dentists
803	Offices of osteopathic physicians
804	Offices of other health practitioners
805	Nursing and personal care facilities
806	Hospitals
807	Medical and dental laboratories
808	Outpatient care facilities
809	Health and allied services, not elsewhere classified

In 1995, the number of wage and salary jobs in the health services industry is projected to vary from 7.3 to 10.5 million, compared with nearly 7.2 million in 1984. (See table 1.) The low scenario shows a barely perceptible 2-percent increase in employment over the 1984–95 period, stagnation that represents a radical departure from past trends. The base case yields a projected employment increase of 26 percent. This is faster than average growth compared with the economy as a whole, but a significant slowdown by health industry standards. Even the high scenario, a 46-percent increase over 11 years, implies a slower rate of job growth than in the past.

The 1995 alternatives have a more pronounced effect on some health industry sectors than on others. At one extreme, hospital employment is projected to decline by 17 percent under the assumptions of the low scenario, from 4.1 million jobs in 1984 to 3.4 million in 1995. Alternatively, under the assumptions of the high scenario, hospital employment would exceed 5 million in 1995, an increase of 24 percent. Underlying the three projection alternatives are significantly different assumptions about hospitals' response to cost pressures and the keenly competitive health care environment. (See exhibit 1.)

Job growth in offices of physicians is projected to outpace the industry as a whole. Nonetheless, under the low scenario, extensive market penetration by health maintenance organizations (HMO's) and imposition of stringent fee restraints are assumed to produce a marked slowdown in growth in this major industry. Wage and salary employment in offices of physicians is projected to vary from 1.2 to nearly 1.5 million jobs in 1995, compared with 908,000 in 1984.

Projected 1995 employment in nursing and personal care facilities varies from 1.3 to nearly 2.1 million wage and salary jobs, up from 1.1 million in 1984. Markedly different assumptions about future directions in long-term care help explain the wide variation in nursing home growth between the low and high scenarios. Strong demand for home health care, a key assumption of all three scenarios, is the principal reason for projected employment growth in health and allied services, not elsewhere classified.

Occupations concentrated in industries that have widely differing growth prospects exhibit the greatest variation under the alternatives. This is particularly true of occupations located for the most part in hospitals and nursing homes. Employment in hospital-based occupations such as respiratory therapist and surgical technician is projected to decline in the low scenario, but grow at a faster than average rate under assumptions of the high scenario. In the case of nursing aides, projected patterns of industry growth are largely responsible for a decline in employment in the low scenario for 1995, compared with much faster than average growth in the high scenario.

Historical trends

Health care has enjoyed a long period of expansion, with continuous growth in funding of services and programs from both the public and private sectors. National health expenditures have grown rapidly, consuming an increasing proportion of the Nation's resources. The growing share of gross national product (GNP) allocated to health, up from 4.4 percent of current dollar GNP in 1950 to 10.6 percent in 1984, is reflected by many indicators of economic activity—personal consumption expenditures on health care, employment, and payroll expenses.

Before turning to an analysis of possible future trends, we should take a careful look at the past. A number of interrelated factors are responsible for the escalation of spending and the expansion of employment in the industry, but incentives built into the health care financing system itself are singularly important. Increases in private health insurance coverage and the introduction of major public programs, including medicare and medicaid, have encouraged greater use of hospital and nursing home care by making such services affordable to segments of the population previously shut out of the health market by price considerations. Methods of financing have shifted as a result of efforts to broaden access to health care. In 1966, the consumer paid directly for half of all personal health care spending, according to estimates by the Health Care Financing Administration. The other half was financed about equally by insurance and public programs. By 1984, public programs accounted for almost 40 percent of all spending; insurance, 31 percent; and the consumer, 28 percent.[4]

The shift of payment responsibility from the consumer to "third parties" such as government and insurance companies is thought to have made patients and providers alike insensitive to the true cost of treatment and care. Both perceive the price of services to be lower than it really is. New programs, new technologies, and new types of personnel have been added because of perceived clinical benefits, with little concern for the cost implications. However, the prevalence of health insurance, as well as the cost of premiums and extent of coverage, differ greatly by sector. Health insurance and public programs currently provide about 90 percent of all spending for hospital care; 72 percent for physicians' services; and 50 percent for nursing home care.

Methods of financing health care have helped shape medical practice patterns and spurred the rapid diffusion of medical technology.[5] For many years, health insurance has given providers an incentive to apply medical technology,

Table 1. Wage and salary employment in the health services industry, 1984 and three projected 1995 alternatives
[Employment in thousands]

Industry	Actual 1984 employment	Projected 1995 employment			Average annual rate of change						
					Historical				Projected 1984–95		
		Low	Base	High	1972–77	1977–84	1982–84	1972–84	Low	Base	High
Total, health services industry	7,188.7	7,325	9,054	10,535	5.3	3.6	1.8	4.3	0.2	2.1	3.5
Offices of physicians	907.5	1,206	1,313	1,450	7.6	5.0	4.9	6.1	2.6	3.4	4.4

[1] Unpublished BLS data.

NOTE: "Unpublished data" do not meet publication standards for accuracy and reliability and therefore are not official Bureau estimates.

Exhibit 1. Assumptions underlying various projection scenarios

Factor	Assumptions		
	Low scenario	Base case	High scenario
Level and distribution of health sector output in 1995	3.0 percent of total private output: $169 billion in 1977 dollars Distribution by sector Sector 140: 47 percent Sector 141: 32 percent Sector 142: 20 percent	3.5 percent of total private output: $200 billion in 1977 dollars Distribution by sector Sector 140: 42 percent Sector 141: 36 percent Sector 142: 22 percent	4.0 percent of total private output: $226 billion in 1977 dollars Distribution by sector Sector 140: 40 percent Sector 141: 36 percent Sector 142: 24 percent
Technology	Same as base case.	Advances that permit complex procedures to be performed on an outpatient basis continue, facilitating shift in delivery of services to nonhospital settings.	Same as base case.
	Technology applied more selectively than in base case.	Advances in diagnostic and treatment techniques continue, fostering greater service intensity (more tests and procedures per patient).	Service intensity somewhat greater than in base case.
	Diffusion of high-cost technologies constrained by restrictive reimbursement policies and hospitals' difficulty in raising capital. Widespread application of technologies that reduce resource utilization.	Rapid diffusion of high-cost technologies continues. Greater effort to develop technologies that reduce resource utilization.	Diffusion of high-cost technologies more rapid than in base case.
Reimbursement	Stringent reimbursement policies established for physician services.	Some tightening of reimbursement for physician services.	Less tightening of reimbursement for physician services than in the base case.
	Stringent constraints imposed on reimbursement for hospital services. Together with HMO expansion, these contribute to reduced demand for inpatient hospital care.	Continued constraints on reimbursement for hospital services, whether through prospective payment or other methods.	Fewer constraints on reimbursement for hospital services than in the base case.
	Stringent constraints on medicare, medicaid, and other third-party reimbursement for nursing home and home health services.	Some added constraints on medicare, medicaid, and other third-party reimbursement for nursing home and home health services.	Fewer constraints on third-party reimbursement for nursing home and home health services than in the base case.
Delivery system:			
Systemwide	Same as base case.	Shift from inpatient to outpatient care continues.	Same as base case.
	Substantial shift away from fee-for-service medicine. HMO's and nonphysician providers account for larger share of office visits for primary care than in the base case.	Moderate shift from fee-for-service medicine to managed care, chiefly because of HMO growth.	Limited shift from fee-for-service medicine to managed care, reflecting slower HMO growth than in base case.

Exhibit 1. Continued—Assumptions underlying various projection scenarios

Factor	Assumptions		
	Low scenario	Base case	High scenario
Delivery system: —continued			
Systemwide	Same as base case.	Some shift in demand for primary care from physicians to other practitioners because of consumer cost sharing and decision making. Contributing factors include wellness and fitness movement; acceptance of nonphysician providers including nurse practitioners, podiatrists, and chiropractors; greater personal responsibility for health, including treatment options.	Same as base case.
	Less increase in demand for elective or nonemergency health services than in the base case.	Moderate increase in demand for health services of an elective or nonemergency nature, such as dental, vision, mental health, counseling, and nutritional services.	Much greater demand for elective or nonemergency services than in the base case because of consumer preference plus changes in insurance coverage and out-of-pocket spending.
	Same as base case.	Nusing home remains principal site for formal long-term care, despite strong growth of home health and community-based programs.	Same as base case.
Hospitals	Occupancy declines sharply, largely because of widespread HMO enrollments and practice patterns that limit hospitalization of HMO subscribers.	Occupancy continues to trend down moderately, then levels out.	Occupancy rises, reflecting less stringent controls on admissions and lengths of stay by HMO's, insurance plans, employers, and other payers.
	Hospitals emphasize inpatient care. Diversification and expansion into outpatient and community-based services and programs inhibited by severe problems in capital formation. Inability to compensate for reduced demand for inpatient care forces some hospitals to cut back or close altogether.	Hospitals provide mix of inpatient and outpatient care. Diversify and expand into nontraditional areas including home health, hospice, nursing home, rehabilitation, alcohol treatment, occupational health and employee assistance, health promotion and wellness, birthing centers, and outpatient surgery. Addition of new services enables hospitals to compensate in part for reduced demand for inpatient care.	Hospitals provide mix of inpatient and outpatient care, and many offer such amenities as luxury suites and gourmet meals. Diversify and expand into nontraditional areas of patient care. Acceleration of trend toward specialization, joint ventures, multihospital networks. Hospitals compete effectively with other providers for outpatients and new sources of revenue.
	Same as base case.	Techniques for managing patient flow, monitoring physician practice patterns, and achieving staffing efficiences are implemented.	Same as base case.
Nursing homes	Bed supply severely constrained by certificate-of-need regulations and investor uncertainties about the nursing home market.	Bed supply increases as certificate-of-need constraints are lifted and investors take a more favorable view of industry profitability.	Bed supply increases substantially as investors take a favorable view of private pay patients' ability to support such expansion.

Exhibit 1. Continued—Assumptions underlying various projection scenarios

Factor	Assumptions		
	Low scenario	Base case	High scenario
Delivery system: —continued			
Physicians	Fee-for-service medicine diminishes in importance. Greater standardization of medical practice as physician services predominantly provided through formal organizations or managed care systems such as HMO's, which establish guidelines for ordering of tests, procedures, and hospital stays.	Fee-for-service medicine continues to predominate despite HMO expansion and growth in preferred provider arrangements.	Fee-for-service medicine flourishes. HMO expansion and growth in preferred provider arrangements is less than in the base case.
Staffing:			
Offices of physicians	Same as base case.	Trends toward group practice, advances in technology, and increased case-mix complexity assumed to produce larger and more diverse medical office staffs. As more nurses, clinical laboratory personnel, radiologic technologists, medical assistants, and others hired to assist with tests and procedures, job growth for clinical support staff expected to outpace that for physicians, and for the industry as a whole.	Same as base case.
	Same as base case.	Office automation, plus availability of software tailored for medical office use, assumed to generate productivity gains and somewhat slower job growth for secretaries, typists, and other clerical staff than for the industry as a whole.	Same as base case.
Offices of dentists	Same as base case.	Little change in use of hygienists, assistants, auxiliary personnel. Trend toward group practice and retail dentistry helps sustain widespread utilization of dental auxiliaries.	Same as base case.
Offices of other health practitioners	Same as base case.	Staffing patterns remain relatively stable because establishment size is assumed to stay small. Among practitioners, job growth assumed to be very rapid in fields where public and professional acceptance of private practice, and lifting of legal and reimbursement restrictions, is most recent. More moderate growth among established practitioners including chiropractors, optometrists, and podiatrists.	Same as base case.

Exhibit 1. Continued—Assumptions underlying various projection scenarios

Factor	Assumptions		
	Low scenario	Base case	High scenario
Staffing: —continued			
Nursing homes	Same as base case.	Efforts to streamline operations assumed to result in joint purchasing and other shared services; more use of computers in clinical, financial, and administrative areas; and smaller proportion of staff in clerical, food service, and housekeeping jobs.	Same as base case.
	Same as base case.	Case-mix assumed to include larger proportion of severely impaired patients, notably Alzheimer's and other chronic "heavy-care" patients, necessitating larger nursing staff.	Same as base case.
	Same as base case.	Increased number of posthospital patients requiring nasogastric feeding, ventilator support, and other advanced nursing skills assumed to produce somewhat greater use of licensed nurses.	Same as base case.
			Greater reliance on private pay patients than in the base case assumed to produce staff changes aimed at extending range of services and improving quality of care; more professionals on staff, notably RN's and LPN's, therapists, physicians, pharmacists, social workers, and activity directors.
Hospitals	Same as base case.	Emphasis on management techniques to schedule patients, procedures, and staff; automated systems to handle clinical, financial, and administrative records; contract services in areas including food service, housekeeping, and clinical laboratory; shared service arrangements in purchasing, laundry, materials warehousing, and computer support.	Same as base case.
	Same as base case.	Larger proportion of hospital staff in professional, managerial, and clinical jobs; fewer in clerical, cleaning and housekeeping, protective service, and other support occupations.	Same as base case.

Exhibit 1. Continued—Assumptions underlying various projection scenarios

Factor	Assumptions		
	Low scenario	Base case	High scenario
Hospitals —continued		Emphasis on identifying new markets and adding new programs and services assumed to contribute to larger proportion of social workers, registered nurses, and therapists; more marketing and public relations specialists as well.	Same as base case.
	Same as base case.	Changes in mix of nursing staff: substantially greater use of RN's, less reliance on licensed practical nurses and aides.	Same as base case.

whether in the form of "little ticket items" such as laboratory tests and X-rays, or costly high-tech procedures such as coronary bypass surgery or magnetic resonance scans. Despite recent changes, fee schedules continue to reward physicians more generously for performing tests and procedures than for providing "cognitive services" such as asking questions, listening, and counseling. Extensive ordering of tests and procedures has traditionally been covered by health insurance, contributing to the increasing diffusion of both old and new technologies.[6]

In addition to the role of insurance, other elements have contributed to health sector expansion. Among them are population growth; rising personal and family incomes; public policies designed to support medical research and expand the supply of health care facilities and personnel; advances in scientific knowledge that result in medical intervention for conditions previously undiagnosed or regarded as untreatable; technological developments that foster the use of sophisticated and expensive medical equipment; and practice patterns that encourage referral to medical specialists and extensive use of costly, high-tech procedures.

Historically, only a small share of total increases in health care outlays can be attributed directly to population aging. But in the future, upward shifts in the age structure are expected to have an effect on health care outlays, particularly those for inpatient hospital and nursing home care.[7] Potential implications of projected growth in the elderly population for health services demand are discussed later, in the section on alternative scenarios.

Output trends. Historical data on the real value of industry output underscore the dramatic expansion of the health sector over the past 25 years. Table 2 documents year-to-year changes since 1960 in the real value of industry output for the total private economy and for the health sector as defined in the BLS economic growth model.[8] In the economic growth system, output is measured as gross domestic output or duplicated output. Health sector output includes total expenditures for products and services of physicians, dentists, and other practitioners such as chiropractors and podiatrists; expenditures for care in private hospitals and nursing homes; purchases of medical and dental laboratory services; premiums paid to health maintenance organizations; and expenditures for services delivered by home health agencies and outpatient care facilities.[9]

Since 1960, growth in health sector output has been sizable and relatively stable compared with total output growth. Despite price increases that have been much higher than the average for the economy as a whole, the health

sector averaged a 5.6-percent annual gain in real output during 1960–84, compared with a 3.3-percent rise in real GNP. Increases in health sector output were greatest in the decade following the 1965 enactment of medicare and medicaid, averaging 7.2 percent a year from 1965 to 1973.

Faster growth in health output than in total private output is responsible for the increasing ratio depicted in chart 1. From 2.0 percent in 1960, the health sector's share of total real output climbed to 3.6 percent in 1982. The drop to 3.5 percent in 1984 shows the effect on this statistic of a vigorously rebounding economy.

Employment trends. Along with a rise in demand for the output of the health sector, employment has grown at a very rapid pace. Health sector employment averaged 5.9-percent annual growth during 1960–84—nearly three times the rate of job growth for the private economy as a whole. Almost 32 million new wage and salary jobs were created in the private economy and of these, nearly 4.6 million or 14 percent, were health sector jobs. Health sector employment has exhibited a remarkably stable pattern of growth for more than two decades, as table 3 shows, and annual gains have consistently outstripped those posted for the total economy. Only twice in the 25 years has job growth in health failed to outpace economywide growth—in 1978 and again in 1984. The health sector's share of wage and salary employment in the private economy has more than doubled as a result, rising from 3.1 to 7.4 percent between 1960 and 1984.

Hospitals have dominated the health care system for decades. From a technological perspective, inpatient hospital care is the cornerstone of our system for delivering complex, acute care services. The hospital is the "workshop" for most physicians and the place where most health professionals receive their clinical training. From an employment perspective, hospitals hire the majority of health industry workers (4.1 of 7.2 million in 1984) and provided more than 40 percent of the 2.8 million new jobs created in the industry between 1972 and 1984. (See table 4.)[10]

From 1972–1982, hospitals posted an average annual job gain of 3.6 percent. During this period, outpatient and clinic care grew—restraining demand for inpatient services—and "service intensity" replaced bed capacity as the driving force behind industry expansion. Service intensity refers to the quantity and complexity of services provided per admission. For example, a cancer patient may require 19 lab tests, 18 pharmacy prescriptions, 3 radiology procedures, and 1 surgical procedure per admission. Contributing to the growth in hospital service intensity throughout the 1970's were the quickening pace of technological advance, changes in treatment approach, and comprehensive insurance coverage coupled with widespread use of cost-based reimbursement.

Gains in the number of tests and procedures per admission more than offset the slowdown in inpatient days during the 1970's, a slowdown caused by shorter hospital stays and growing substitution of outpatient for inpatient services. Outpatient visits to community hospitals rose by 21 percent between 1973 and 1983, compared with a 14-percent increase in inpatient admissions.[11] Hospital employment grew 38 percent over the same period, largely because of significant growth in laboratory, diagnostic, surgical, and other services rendered per patient day.

[1] Economic growth sectors 140 (Doctors' and dentists' offices), 141 (Hospitals), and 142 (Medical services, not elsewhere classified). Data include veterinary services, exclude offices of optometrists.

Employment in offices of physicians and osteopathic physicians rose more than twice as fast as hospital employment during 1972–84. Among the factors contributing to rapid growth over the entire period were substantial increases in the supply of practitioners, widespread insurance coverage for medical and surgical care, greater service intensity, technological developments that permitted substitution of ambulatory services for inpatient hospital care, and emphasis on the use of nurses, medical assistants, and other support staff to extend the physician's productivity. The aging of the population also contributed to job growth inasmuch as both the number of physician visits per capita and intensity of services per visit are relatively higher for the elderly. Some of the growth registered in offices of physicians and osteopathic physicians is a statistical artifact, a consequence of practitioners' increasing propensity to incorporate for tax and other business reasons. The resultant shift in class-of-worker status (from self-employed practitioners, who are not included in these employment estimates, to wage and salary workers, who are) affects the trend data displayed in table 4. However, it is impossible to quantify the impact of this factor on industry growth. Physicians currently account for approximately 19 percent of wage and salary employment in offices of physicians and a somewhat smaller percentage of employment in offices of osteopathic physicians.

Historically, employment has risen much faster in nursing and personal care homes than in hospitals. Increased medicaid coverage for nursing home care, State policies of transferring patients from mental hospitals to nursing homes, growth in real incomes, and an aging population help explain the very rapid rise in the industry's employment during the early 1970's.[12] Nursing home employment increased at an average annual rate of 7.8 percent from 1972 to 1977, then slowed as numerous States imposed controls on nursing home construction and otherwise sought to limit medicaid outlays. Additions to nursing home capacity have not kept up with population growth in recent years, and the disparity may grow, according to industry observers. Together with low medicaid reimbursement rates in many States, changes in tax laws have made nursing home construction less attractive to investors.

There has been little change in recent years in the way nursing home care is financed: about half of the money comes from patients and their families, and the rest comes from public programs, of which medicaid is by far the most important. Because additional nursing home beds may generate higher levels of medicaid spending, States have an interest in curtailing growth. Some have done so by cutting reimbursement, implementing stringent certificate-of-need policies, and instituting moratoria on new nursing home construction.[13]

Changes in the industry's structure have occurred since Federal subsidies for nursing home care began in 1956, under the Old Age Assistance program. Changes include an increasingly sophisticated medical orientation in nursing home care, a shift from government-owned to proprietary homes, and, more recently, a growing concentration of ownership in multifacility chains. The more sophisticated medical orientation reflects medicaid requirements for covered care, and State as well as Federal efforts to improve quality by enforcing staffing standards. Both skilled and intermediate levels of medicaid-covered care require more nursing involvement than the small old-age homes from which the industry evolved.[14]

The increasing professionalism of nursing home care, over the decade of the 1970's, produced an increase in staff-patient ratios. These ratios interact with the bed supply (that is, number of residents) to determine the rate of employment growth. According to the National Center for Health Statistics, the number of full-time equivalent employees in facilities with 25 beds or more increased 98 percent from 1969 to 1980, while the number of nursing

home residents rose by 75 percent. The number of full-time equivalent employees per 100 beds rose from 55.0 in 1969 to 62.9 in 1980.[15] However, the overall increase in the staff-to-bed ratio masks significant variation among facilities. Staffing ratios vary according to such factors as degree of illness, payment source, facility size, certification, ownership, and commitment to quality care.

Three industries experienced exceptionally rapid job growth over the 1972–84 period. The industries and their average annual employment gains are as follows: offices of other health practitioners (10 percent), outpatient care facilities (12 percent), and health and allied services, not elsewhere classified (15 percent).

Offices of other health practitioners is a diverse industry that includes a wide variety of health professionals in solo or group practice: chiropractors, optometrists, podiatrists, nurse practitioners, midwives, physical therapists, occupational therapists, speech pathologists and audiologists, dietitians and nutritionists, social workers, and psychologists. No less diverse is the outpatient care facilities industry, which includes HMO's, community mental health centers, family planning clinics, urgent care centers, outpatient surgical centers, birthing centers, and freestanding hospices. Health and allied services, not elsewhere classified, is a relatively homogeneous industry, comprising home health agencies and blood banks.

Job growth in these settings is consistent with steadily increasing acceptance of nonphysician providers, together with the gradual shift away from the hospital as the exclusive site of complex health care. Throughout the decade of the 1970's, ambulatory care alternatives became more important. Technological developments made it possible to provide increasingly sophisticated care on an outpatient basis, while changes in insurance coverage and benefits made such care financially attractive to health care consumers. The pace of the shift from inpatient to outpatient care has accelerated dramatically in recent years because of the emphasis on providing cost-effective health services.

Recent developments

Increased public and private sector emphasis on health care cost containment is the most important development in recent years. Health economists and policymakers had long been concerned about rapidly rising health care expenditures, but it was not until the early 1980's that the combined impact of inflation, recession, soaring outlays for employee health benefits, threatened medicare insolvency, and State fiscal crises produced significant action by business, labor, and government. The hospital payment system mandated by the Social Security Amendments of 1983, medicare's prospective payment legislation, is the leading example of such action.

Medicare's system links payment for hospital inpatient services to rates for each of 467 diagnosis-related groups (DRG's). Hospitals know in advance how much medicare will pay for the treatment of a patient with a particular diagnosis. Under the previous cost-based retrospective system, hospitals were reimbursed for whatever they spent. Because hospitals now bear the loss if the cost of treatment exceeds the fixed medicare payment, it is in their interest to be selective about the patients they admit, scrutinize tests and procedures, discharge patients as soon as possible, and encourage greater use of outpatient services. Not surprisingly, hospitals have responded to the new system with programs for managing admissions and patient flow, monitoring physician practice patterns, and controlling operating costs.

Cost containment initiatives figure prominently among the reasons for a recent decline in hospital employment. Average annual employment in private, State, and local government hospitals stood at 4,040,900 in 1985, 110,600 fewer jobs than in the peak year of 1983. More than 73,000 hospital jobs disappeared in 1984, and 37,000 more in 1985. While no single factor can fully explain the loss of hospital jobs, management initiatives to reduce labor costs (about 50 percent of community hospitals' operating budgets) through such belt-tightening measures as staff cuts, hiring freezes, greater use of part-time and on-call staff, and a shift to contract services are partly responsible. However, a drop in hospital utilization—notably inpatient admissions, staffed beds, and length of stay—is the underlying factor.

Data from the American Hospital Association indicate a shift in utilization since the beginning of 1983: shorter hospital stays by elderly patients and a sharp decline in admissions of patients under age 65.[16] The average length-of-stay of patients age 65 and above fell from 11.1 to 10.1 days between 1977 and 1982, then dropped to 8.8 days at the end of 1984. Shorter hospital stays for elderly patients appear to be the direct result of incentives to hospitals in the DRG system, although technology and changing medical practices may be responsible as well. The use of lasers, for example, has reduced recovery periods and lengths-of-stay for certain types of eye surgery. The availability of advanced techniques for delivering antibiotic and nutrition therapy at home may also speed discharge.

The reasons for falling admissions of patients under age 65 are not well understood.[17] The most likely causes are utilization review and the expanded use of consumer cost-sharing features built into employee benefit plans, improved health insurance coverage for ambulatory care and the growth of alternative care settings, increased public awareness of the importance of avoiding hospitalization when possible, plus reduced access to care for the poor. Limitations on medicaid program eligibility and increased financial barriers to serving the uninsured may be holding down hospital use by these groups.[18] In addition, economic weakness in regions with heavy concentrations of industries experiencing poor recovery may be an element.[19]

Hospitals confronted with reduced demand for inpatient services have begun to develop a business strategy[20] that emphasizes joint ventures, mergers, specialization, and introduction of new programs and services. Home health care is the alternative service offered by more hospitals than any other, according to several recent surveys.[21] Other services being implemented by hospital administrators include hospice care, nursing home units, rehabilitation, alcohol treatment, occupational health and employee assistance, birthing centers, outpatient surgery, cancer screening, and geriatric assessment. A number of hospitals have set up wellness and fitness centers that offer medical and physiological testing, assessment of lifestyle-related health risks, health education, and sports medicine.

Other changes, too, are occurring in the health care environment. One of the most striking is the rise in HMO enrollments, up from 10 to 21 million subscribers between 1981 and 1985.[22] Industry observers expect continued rapid growth. There is a wide range of opinion on the extent to which HMO's will penetrate traditional health care markets (many analysts expect HMO enrollment to peak at 30 to 35 million by 1995, but some estimates are considerably higher).

HMO's are prepaid health insurance plans designed to deliver affordable and comprehensive medical services to enrolled members. Starting from the premise that physicians govern a substantial portion of total health spending by virtue of their authority to hospitalize, order batteries of tests, and so forth, HMO's and other systems of "managed care" seek to control utilization by influencing physicians' ordering behavior. Comparative studies have found that HMO enrollees pay 10 to 40 percent less than those enrolled in fee-for-service health insurance plans. In addition, the hospitalization rate for people enrolled in HMO's is considerably below the rate for those enrolled in traditional fee-for-service plans. This is attributed to HMO emphasis on preventive health care, broad ambulatory coverage, multispecialty staff, and risk-sharing by HMO physicians, who are offered incentives to reduce unnecessary hospitalization.

There are three types of HMO's. The first, called a "staff model" HMO, delivers medical services at one location or more, using physicians directly employed by the organization. The second kind, known as an "individual practice association" (IPA), makes contractual arrangements with doctors in private practice who treat HMO members in their own offices. The third, the "group" or "network" HMO, involves contractual arrangements between the HMO and two group medical practices or more.

Long-term care constitutes the third major area of change in recent years. Heightened awareness of the "greying" of America has focused attention on the distinctive needs of individuals who are disabled, chronically ill, or functionally impaired. By no means are all of these people elderly. Nonetheless, the need for long-term care services is strongly associated with age. Elderly persons, by virtue of their high risk of disabling conditions, are the primary recipients of long-term care services, whether formal or informal. In recent years, both the number and proportion of the population 65 and older have increased significantly (table 5), a demographic trend of major proportions that will continue well into the next century. Within the 1984–95 timeframe that is the focus of this article, projected growth in the number of persons 85 and above merits special attention because of the implications for long-term care, in general, and for the nursing home sector in particular.

At advanced ages, there is a high risk of chronic disease, limitations in mobility and ability to perform everyday activities, and the loss of spouse or other family helpers. The following tabulation, based on 1977 data,[23] reveals the sharp increase in nursing home use after age 85:

	Percent of age group residing in nursing homes	
	Men	*Women*
All age groups	0.4	0.8
Under 65 years	0.1	0.1
65 years and over	3.0	5.9
65 to 74 years	1.3	1.6
75 to 84 years	4.0	7.6
85 and over	17.8	26.2

Utilization rates that take marital status into account underscore the role of informal social supports in precipitating institutionalization, on the one hand, or delaying it, on the other. Elderly people with serious health problems are more likely to enter a nursing home if they are widowed or single than if they are married. Further, it appears that substantially greater use of nursing homes by women than by men is not simply because of women's greater longevity, but also reflects their greater likelihood of becoming widowed.

Traditional health and social service providers have begun to modify their programs to respond more effectively to the service needs of the elderly. Many hospitals, for example, regard the elderly as a market opportunity and are expanding their home health and community outreach programs accordingly.[24] Family service agencies, too, are revamping their offerings as clients' needs change. A broad range of long-term care initiatives has been launched in recent years, many with foundation support or on a demonstration basis. Most of these seek to improve community-based services, strengthening the network of formal and informal care givers whose services permit people with disabilities to remain at home. Community-based long-term care is likely to play a more prominent role in 1995 than it does today, because of consumer preference and provider flexibility. However, the potential impact on the nursing home industry is difficult to assess, for it is unclear to what extent community-based care complements, rather than substitutes for, institutional care.

Table 5. Growth of the older population, actual and projected, 1950–95

[In thousands]

Age group	1950	1960	1970	1980	1984	1990	1995
All ages	150,697	179,323	203,302	226,505	236,416	249,657	259,559
Under 65	138,427	162,763	183,322	200,960	208,431	217,960	225,672

Alternative scenarios

The size and structure of the health industry in 1995 will be shaped by events that are still unfolding. Despite considerable uncertainty about the future, a number of relevant factors can be identified and assessed. This section begins with a discussion of three such factors: the impact on overall demand for health services of HMO expansion and changes in physician reimbursement; prospects for hospital utilization; and directions in long-term care financing. Qualitative assumptions consistent with each of three growth scenarios (low, base, and high) are presented in exhibit 1. The section then explains how the growth scenarios were translated into alternative projections of health industry employment in 1995.

A shift from traditional, fee-for-service medicine to systems of managed care is underway. Indicative of this trend are the emergence and very rapid growth of such organizations as HMO's, IPA's, preferred provider arrangements, and medicaid "gatekeeping" schemes in which primary-care physicians control referral to specialists. Systems such as these limit consumer choice and set guidelines for physicians and other practitioners in order to gain greater control over service utilization—for example, lab tests, X-rays, and hospital admissions. According to one estimate, patient use of traditional fee-for-service medicine, an estimated 94 percent in 1982, could drop to 70 percent by 1987.[25] Depending on the extent to which managed care systems replace fee-for-service medicine by 1995, practice patterns, establishment size, and staffing in offices of physicians could change. Furthermore, the shift to managed care may reduce future demand for hospital care. It is generally agreed that the fee-for-service method of paying physicians encourages more hospitalization and greater use of tests and procedures.

Much will depend on future developments in health care financing, including changes in reimbursement patterns and regulation of physicians' fees. Reform of the medicare payment system for physician services lies ahead, with extension of prospective payment to physicians being one of a number of options under consideration. Each of the three growth scenarios embodies a different set of assumptions about the future role of fee-for-service medicine, on the one hand, and constraints on physician reimbursement, on the other. (See exhibit 1.)

As noted, hospital utilization is down sharply, according to such standard measures as admissions, inpatient days, and average length of stay. Recent reductions in hospital use are attributed to rising HMO enrollments, greater consumer cost sharing, and stricter utilization review procedures, as well as to medicare's prospective payment system. However, whether the decline will continue over the long run is questionable.[26] For one thing, technological progress could lead to greater—rather than less—hospitalization as medical possibilities are enhanced.

The aging of the population will put pressure on demand for hospital care during the next 10 years unless health status, practice patterns, or both, change a great deal. Hospital use is significantly greater for the elderly than for persons under 65; elderly people are hospitalized more frequently and stay there longer. In addition, the rapidly growing population 85 years and above uses twice as many hospital days per capita as persons aged 65 to 74 years. One reason for this is the presence of multiple health problems in the very old, which produce much longer hospital stays. Another is a dramatic increase in the number of surgical procedures performed on elderly patients, as technological advances continue to make surgery less risky. The growing importance of outpatient surgery could have a dampening effect on demand for inpatient hospital care, depending on future patterns in outpatient surgery on the elderly.

Also contributing to uncertainty about future trends in hospital use is the issue of length of stay. Recent decreases have been dramatic, but will they continue? We may be approaching the limit for shortening the hospital stays of elderly patients, who account for approximately 40 percent of all hospital days of care. Among patients under 65, the proportion in HMO's—together with hospitalization guidelines adopted by HMO's—will play a significant role in future length-of-stay trends. Because so many factors are at work, the three growth scenarios reflect widely varying assumptions about the level and nature of future demand for hospital care. (See exhibit 1.)

What has been termed the "nursing home dilemma" centers on the conflict between the demographics of population aging, on the one hand, and the economics of the nursing home industry, on the other.[27] The number of people seeking admission to nursing homes can be expected to continue to rise for a number of reasons, but very rapid growth in the population over the age of 85 is the key factor. Americans age 85 or above are projected to number 4.1 million in 1995, up from 2.6 million in 1984, as table 5 shows. This represents a 57-percent gain, markedly faster growth than that projected for any other age group.

The prospect of explosive growth in the population needing long-term care is widely acknowledged, but future directions in financing and service delivery are cloudy. All payers—Federal, State, and private—are reluctant to expand benefits or push for significant improvements in long-term care financing because of concern about "uncontrollable" costs. Uncertainty about the potential costs of community-based long-term care programs, together with concern about increasing expenditures under medicaid and other public programs that currently finance much institutional long-term care, have shifted attention to private sector initiatives that might relieve fiscal pressures on public programs and, at the same time, improve the elderly's ability to finance long-term care. Some of the options that have emerged in recent years as feasible alternatives for financing long-term care include private health insurance, health care Individual Retirement Accounts, life care communities, and home equity conversion.[28]

Interest in private long-term care insurance appears to be mounting.[29] This method of financing long-term care is backed by the American Health Care Association and the American Association of Retired Persons, among others, and many States—faced with mounting medicaid expenditures for nursing home care—are expressing interest in it. Private insurance for long-term care has been suggested not only because of growing fiscal constraints on public program expenditures, but more basically because private insurance coverage is currently available for a wide variety of health care services, but it is generally not available for long-term care services or for the costs associated with chronic illnesses such as Alzheimer's disease. Tremendous growth would be necessary before private long-term care insurance covered a substantial portion of nursing home costs; currently, such insurance pays about 1 percent. However, if significant developments occur in this area it could dramatically alter the long-term care picture in the future.

Underlying the base case, as exhibit 1 shows, is the assumption that demographic pressures will force some resolution of the financing, reimbursement, and certificate-of-need issues that have slowed nursing home growth in recent years. The low scenario assumes that uncertainty will continue to prevail, discouraging investment and putting a brake on industry expansion despite very rapid growth in the elderly population. The high scenario makes relatively optimistic assumptions about public and private spending for institutional long-term care.

Moving from the qualitative assumptions summarized in exhibit 1 to alternative projections of industry and occupational employment was a procedure that encompassed several steps. As the first step, data points above and below the base case level were selected to represent projected output under high and low scenario conditions. The output projections were then used, first in conjunction with the Bureau's input-output model and then with its industry-occupational matrix, to generate alternative projections of wage and salary employment by detailed health industry and occupation. The five steps that make up the projections process are summarized below.

1. Set alternative levels of projected output for the private health sector by projecting the ratio of health sector to total private sector output. The moderate-growth projection (3.5 percent in 1995) was chosen for the base case; data points above (4.0 percent) and below (3.0 percent) the base case were selected to represent the high and low scenarios. This determined the total dollar value

of goods and services that would be produced by practitioners and establishments in the economic growth sectors (doctors' and dentists' offices, hospitals, and medical services, not elsewhere classified) under varying assumptions about health system performance in 1995.

2. Set alternative levels of projected output for each of the three economic growth health sectors by varying the distribution of total health sector output.

3. Derive estimates of projected employment for each of the detailed economic growth sectors. That is, estimate the number of wage and salary workers required to produce the projected level of output established in step 2.

4. Translate projected employment in the economic growth sectors into industries categorized by Standard Industrial Classification and adjust these data to include State and local hospitals and offices of optometrists and exclude veterinary services, so these data conform to the configuration of the National Industry-Occupational Matrix.[30]

5. Convert the industry employment data developed in step 4 into projections of occupational employment by applying staffing patterns consistent with each of the alternative scenarios.

Output and employment

In 1984, services produced by the private health sector were valued at more than $141 billion in constant dollars, or 3.5 percent of the Nation's total private sector output that year. By 1995, under the moderate-growth projections discussed in the November 1985 issue of the *Review*, output for the private economy as a whole is expected to reach $5.6 trillion. The health sector's share is projected to range from $169 billion to $226 billion.

Table 6. Health sector output and employment under alternative projection scenarios, 1984 and projected 1995

Year	Sectors 140–142	Sector 140	Sector 141	Sector 142
	Output (in millions of 1977 dollars)			
1984	$141,174	$58,882	$54,927	$27,365
Projected:				
1995 Low	169,311	79,782	54,927	34,602
1995 Base	199,705	84,591	70,826	44,288
1995 High	225,748	90,298	81,269	54,180
	Average annual rate of change (in percent)			
1984–95 Low	1.7	2.8	0.0	2.2
1984–95 Base	3.2	3.3	2.3	4.5
1984–95 High	4.4	4.0	3.6	6.4
	Employment (in thousands of wage and salary jobs)			
1984	6,141	1,396	2,994	1,751
Projected:				
1995 Low	6,473	1,842	2,441	2,190
1995 Base	8,049	1,972	3,253	2,824
1995 High	9,468	2,125	3,870	3,473
	Average annual rate of change (in percent)			
1984–95 Low	0.5	2.5	−1.9	2.1
1984–95 Base	2.5	3.2	0.8	4.4
1984–95 High	4.0	3.9	2.4	6.4

NOTE: Sector 140 — Doctors' and dentists' offices (SIC 801, 802, 803, 8041)
Sector 141 — Hospitals (SIC 806)
Sector 142 — Medical services, not elsewhere classified (SIC 8049, 805, 807, 808, 809, 074)

Base case. Efforts to constrain spending are expected to dampen rising demand for health services under the assumptions of the base case. As table 6 shows, health sector output is projected to increase at an annual rate of 3.2 percent over 1984–95. This is markedly slower growth than in the past (compound growth rates): 5.6 percent during 1960–80, 4.9 percent over 1970–84, and 3.9 percent, 1977–84. The base case assumes no change between 1984 and 1995 in the share of private sector output generated by the health sector. (See chart 1.) A departure from historical trends, this assumption seems plausible in light of intense cost containment pressures and excess hospital capacity. Wage and salary employment is projected to grow at an annual rate of 2.5 percent under the assumptions of the base case, less than half the rate attained during 1970–84. With labor costs constituting providers' largest single outlay, efforts to achieve efficiencies in a cost-conscious climate are bound to target staff.

Low scenario. The low scenario assumes cost containment measures that alter medical practice patterns; restrictive reimbursement policies, declining admissions, and problems in capital formation for hospitals; and deceleration in the rate of spending for institutional long-term care. Private health sector output is projected to grow at an annual rate of 1.7 percent, roughly one-third the rate posted during 1970–84. The output of the health sector is assumed to decline as a percentage of total private sector output. A decline in this statistic is unprecedented. Wage and salary employment in the health sector is projected to grow at an annual rate of only 0.5 percent over the 1984–95 period under the low scenario.

High scenario. Output of the private health sector is projected to grow at an annual rate of 4.4 percent under the high-scenario assumptions, about the rate attained during the latter half of the 1970's. From a 1984 level of 3.5 percent of private sector output, health sector output is projected to reach 4.0 percent by 1995, continuing the long-term upward trend, but at a slower rate than in the past.

Compared with the base and low scenarios, the high scenario offers a more optimistic picture of prospects for hospital sector expansion. In addition, it assumes exceptionally rapid growth of the nursing home and home health industries because of significantly increased spending for long-term care. (See exhibit 1.) Wage and salary employment is projected to grow at an annual rate of 4.0 percent, slightly less than the 4.2-percent rate posted during 1977–84.

Projected 1995 employment in the health industry, under the alternative sets of assumptions summarized in exhibit 1, varies from 7.3 to 10.5 million wage and salary jobs. In each alternative, projected growth is slow by historical standards, as table 1 shows. The projected increase of nearly 1.9 million health industry jobs under the assumptions of the base case represents an annual growth rate of 2.1 percent during 1984–95, less than half the rate posted for 1972–84. The high scenario, which generates approximately 3.3 million new health industry jobs, assumes a rate of growth roughly equivalent to that attained over the 1977–84 period.

Historical patterns of job growth vary greatly across the nine health industries, and this variation carries forward in the projections to 1995. Detailed industry discussions follow.

Offices of physicians (SIC 801). The annual rate of job growth in offices of physicians is projected to outpace the health industry as a whole under all three scenarios, although several other sectors are projected to experience much faster growth. In 1995, wage and salary employment in this industry is projected to range from 1.2 to nearly 1.5 million jobs, a difference of 20 percent between the low and high scenarios. Helping to explain the variation is the low scenario assumption of market penetration by HMO's and the shift to managed care, trends which are expected to dampen demand for medical services. At least partially offsetting the dampening, however, is rapid expansion of IPA and network-type HMO's, which contract with physicians in private practice to provide medical care to their members. Essentially unchanged policies regarding reimbursement for physicians' services is a key assumption of the high scenario.

Offices of dentists (SIC 802). Wage and salary employment in offices of dentists is projected to be roughly the same under all three 1995 scenarios.

Offices of osteopaths (SIC 803). Osteopathic physicians are likely to be affected similarly to other physicians by the assumptions that underlie the alternative scenarios. Employment in this small industry is projected to vary by approximately 26 percent between the low and the high scenarios. Under the base case, 1995 wage and salary employment is projected to reach 44,000, rising from a 1984 level of 30,000.

Offices of other health practitioners (SIC 804). Consumer acceptance of nonphysician providers is so well-established, and the trend toward alternative delivery systems is so strong, that continued rapid expansion is assumed under each scenario, placing offices of other health practitioners in the ranks of the fastest-growing health industries. Wage and salary employment is projected to increase at a rate nearly double that for offices of physicians and osteopaths.

The wide range in projected 1995 employment—a difference of nearly 57 percent between the low and high scenarios—is largely explained by different assumptions about third-party reimbursement. The high scenario assumes more favorable coverage for the services of nonphysician providers than is the case today, for example, more liberal mental health benefits.

Nursing and personal care facilities (SIC 805). Second only to hospitals in employment size, the nursing and personal care sector provided more than 1.1 million wage and salary jobs in 1984. Projected employment in 1995 ranges widely from 1.3 to nearly 2.1 million jobs.

Hospitals (SIC 806 plus State and local government hospitals). From a level of 4.1 million wage and salary jobs in 1984, hospital employment is projected to increase more slowly than average under the base case. Employment is projected to decline sharply in the low scenario, dropping to 3.4 million jobs in 1995. The high scenario paints an entirely different picture: faster than average growth is projected to create 1 million additional hospital jobs over the 1984–95 period.

The base case assumes a downturn in use of inpatient services as occupancy rates slide. Offsetting this is an expansion of outpatient services and diversification into nontraditional areas such as home health. The base case also assumes that hospitals' ability to restructure to take advantage of emerging market opportunities is constrained by problems in raising capital. Limited access to needed capital is an even greater constraint in the low scenario. However, the key assumption of the low scenario is the shift to managed care, which produces stringent controls on hospital utilization by HMO subscribers and others in managed care systems. These assumptions are outlined in exhibit 1.

Medical and dental laboratories (SIC 807). The alternative scenarios sketched here have a limited effect on projected employment in this small industry. The volume of laboratory work ordered by physicians may be affected by changes in reimbursement levels and guidelines, to the extent that testing has been implicated as a source of rising health care costs. However, other factors besides physicians' ordering practices determine how much laboratory work is sent to commercial laboratories for analysis.

Among these are the economics of in-house versus contracted clinical laboratory services for hospitals; advances in medical diagnostics that increase the amount of testing as new tests are developed; changes in case mix—an increase in the number of patients with illnesses that require extensive laboratory workups, for example; and the availability of portable analyzers that can be installed in the physician's office or clinic. The potential impact of further developments in laboratory automation must also be kept in mind. Automation of chemistry and hematology, two of the most labor-intensive functions in the clinical laboratory, is already well-established.[31] Microbiology, immunology, and serology are candidates for widespread automation in the coming decade. Prospects for even greater diffusion of automated systems help explain the very modest growth projected for this industry under all scenarios.

Outpatient care facilities (SIC 808). This small industry includes HMO's, outpatient surgical centers, diagnostic imaging centers, urgent care centers, alcoholism treatment centers, community mental health centers, family planning clinics, and other outpatient facilities. Employment is projected to rise much faster than average under all three scenarios. Under the base scenario, for example, employment is projected to increase at an annual rate of 6.7 percent, more than triple that projected for the health industry as a whole. Exceptionally rapid growth in the base case reflects not only the shift to outpatient care, but the success of providers in this industry sector in capturing much of the market.

Turning to the high scenario, favorable reimbursement policies (expanded coverage for mental health and alcoholism treatment, for example) and higher overall levels of health care spending are expected to contribute to very rapid projected growth. Employment in this industry might be higher still under the high scenario, were it not for the assumption that hospitals will set up a broad range of outpatient services—competing effectively in the outpatient market with freestanding outpatient facilities, on the one hand, and large group medical practices, on the other.

Health and allied services (SIC 809). This rapidly growing industry includes home health agencies and blood banks. It seems reasonable to assume that home health care—not blood banking—is responsible for recent recordbreaking growth in this industry. This assumption is carried forward in each projection scenario. On the one hand, intense pressure on the demand for services provided by home health agencies is expected to persist because of the aging of the population, consumer preference, incentives to discharge hospital patients as soon as possible, and changes in private insurance and medicare coverage that make home health more affordable for patients recovering from acute illnesses. Second, blood banking is ripe for automation. Industry observers anticipate that automated laboratory systems will be used by the early 1990's, with likely displacement of blood bank employees.

The annual rate of employment growth in this industry is projected to outstrip the rest of the health services industry under all three scenarios. According to the base case, employment is projected to double during 1984–95, rising from 151,000 to 315,000 jobs. Increased public and private spending for home health care is a key assumption of the base case. The high scenario assumes an increase in out-of-pocket spending for home health services for patients not eligible for insurance benefits, those with chronic conditions and long-term care needs, for the most part.

Occupational projections

In the National Industry-Occupational Matrix, occupational employment in the target year is determined by projected industry employment, on the one hand, and projected staffing patterns, on the other. To project staffing ratios, first, 1984 staffing patterns ("industry-occupational ratios") for each of the nine matrix health industries were analyzed. This step included comparing the 1984 data with patterns from earlier years and other sources, including the Current Population Survey and the annual American Hospital Association survey. Next, projected 1995 ratios were developed, consistent with the assumptions of the base case about future trends in health care financing and service delivery. For example, this involved judgments about the impact of technology, use of contract services and temporary employees, and trends in professional practice, case mix, and length of stay.

The procedure was repeated under staffing assumptions consistent with both the low and high scenarios. For example, staffing patterns for nursing and personal care facilities were adjusted to reflect the impact of more private-pay patients in the high scenario. Facilities serving these patients would presumably offer more amenities, as well as more intense therapy, nursing, recreational, and social services. Some of these assumptions are presented in exhibit 1.

Next, occupational staffing patterns were applied to the industry totals shown in table 1. This generated three sets of industry-occupational matrices for each of the nine health industries, plus industrywide estimates of 1984 and projected 1995 employment for 200 detailed occupations. Industrywide estimates for selected health occupations are shown in table 7.

A wide range of growth prospects appears when projected growth under each of three alternatives is compared with the average rate of job growth for the economy as a whole, 1.3 percent a year over the 1984–95 period. For example, employment of health services managers, physicians, physician assistants, and medical assistants is projected to grow faster than average even in the low alternative. Except for health services managers, who are dispersed across all nine health industries, these occupations are concentrated largely in offices of physicians and osteopathic physicians, industries that are projected to grow considerably faster than the health services industry as a whole under the low scenario assumptions. In addition, most of these occupations are projected to increase as a proportion of industry employment as HMO's, group medical practices, and other large establishments increasingly dominate medical practice.

Considerable attention has been paid to new job opportunities in ambulatory and outpatient settings including home health programs, health maintenance organizations, urgent care centers, wellness and fitness programs, and life care communities. The alternatives presented here show that in the case of registered nurses, the hospital will remain the major source of employment in 1995, despite the emergence of alternative delivery systems and the expansion of long-term care.

Because recent nursing school graduates are a major source of supply for the profession,[32] nursing education will confront vastly different challenges depending on the rate of industry growth in the decade ahead. The number of new jobs for registered nurses varies widely according to the projection scenario, as table 7 shows. As few as 72,000 additional registered nurse jobs—or as many as 650,000—might be created in the health services industry between 1984 and 1995, depending on the alternative selected. Because supply and demand are roughly in balance in the base case, realization of the high scenario could entail such measures as stepped-up recruiting of inactive nurses, wage incentives, and expansion of training opportunities for nurses. Nursing homes would face a formidable recruiting challenge. Conversely, the sluggish job growth depicted by the low scenario would mean less favorable job prospects in nursing overall, depending on replacement needs and on how rapidly nursing school enrollments responded to an oversupply.

For a number of occupations, the "shrinkage" of the hospital industry under the assumptions of the low scenario would mean an employment decline between 1984 and 1995. Such occupations include licensed practical nurses, nursing aides, psychiatric aides, clinical laboratory technologists and technicians, EKG technicians, respiratory therapists, surgical technicians, social workers, dietitians, dietetic technicians, pharmacists, and recreational therapists. Careful tracking of hospital industry trends is advisable for policy makers and planners concerned with occupations in this group.[33] For if instead of the low scenario, the high-scenario assumptions are realized, prospects are for faster-than-average job growth in many of these occupations. This would require a totally different response from vocational and higher education planners, as well as from industry officials responsible for recruitment and in-service training.

Table 8 depicts projected change in employment for health workers by broad occupational group. Employment in most groups at the lower end of the skill ladder is projected to grow more slowly than the industry average under each of the three alternatives. This continuation of a long-term trend reflects changes in case mix and patterns of patient care, use of contract and shared service arrangements, and widespread application of computers for clinical, financial, and administrative purposes.

Conclusions

Although one can imagine other ways that the next decade may unfold, the three scenarios presented here are representative possibilities. The base scenario assumes that output and employment growth will be somewhat below historical levels, in general because of increased emphasis on cost

Table 7. Wage and salary employment in the health services industry, selected occupations, 1984 and three projected 1995 alternatives

Occupation	Actual 1984 employment	Projected 1995 employment			Average annual rate of change, 1984–95 (in percent)		
		Low	Base	High	Low	Base	High

Health services and related	1,349,213	1,426,970	1,767,586	2,068,225	0.5	2.5	3.9
Personal services	32,012	34,619	46,564	54,107	0.7	3.3	4.9
Protective services	35,680	26,368	33,849	38,344	−2.1	−0.5	0.9
All other services	133,206	130,831	168,251	198,761	−0.2	2.1	3.7
All other occupations	288,917	284,763	351,360	407,166	−0.1	1.8	3.2

containment. More explicit assumptions involve some growth and rapid diffusion of technology, but an emphasis on that which saves resources, as opposed to resource-intensive high-cost technology. Some tightening of physician reimbursement is assumed, as well as a moderate continuation of the shift from fee-for-service physician care to HMO care. Hospital occupancy is assumed to continue its recent downward trend but then to level, with a shift towards heavier employment of skilled workers relative to clerical, janitorial, and other workers. The bed supply in nursing homes is assumed to increase as regulation of that industry eases. Other assumptions generally involve a moderate continuation of present trends.

Although it lies between the low and high scenarios, the base case does not represent a midpoint. With respect to prospects for job growth, the low scenario may be more extreme on the unfavorable side than the high scenario is on the favorable side. In any event, the sharply contrasting futures depicted by the low and high scenarios make it clear that the outlook is uncertain. The health services industry is in transition, and it remains to be seen whether organizational forms and approaches that take hold over the coming decade will entail gradual and moderate changes in employment levels, staffing patterns, and educational requirements—or abrupt, even disruptive, change. For employers, educators, and policy makers who seek to plan effectively for the future, staying abreast of industry developments has never been more necessary. ☐

[8] Economic growth sectors 140, 141, and 142 make up the health sector. Coverage is as follows: sector 140, Doctors' and dentists' offices; sector 141, Hospitals; sector 142, Medical services, not elsewhere classified.

The industry composition of each sector, as defined by the 1972 Standard Industrial Classification (SIC) is:

Sector 140-Doctors' and dentists' offices	SIC 801-Offices of physicians SIC 802-Offices of dentists SIC 803-Offices of osteopathic physicians SIC 8041-Offices of chiropractors
Sector 141-Hospitals	SIC 806-Hospitals (excludes Federal, State, and local government hospitals)
Sector 142-Medical services, not elsewhere classified	SIC 8049-Offices of health practitioners, not elsewhere classified SIC 805-Nursing and personal care facilities SIC 807-Medical and dental laboratories SIC 808-Outpatient care facilities SIC 809-Health and allied services, not elsewhere classified SIC 074-Veterinary services

SIC 8042, Offices of optometrists, is not included in the economic growth health sectors.

[9] Output includes primary (health care) and some secondary products and services such as nonmedical testing performed in medical laboratories. This measure of industry output differs from a measure of commodity output because of these secondary products.

This measure is gross or somewhat duplicated in that some intermediate products or services may be counted more that once in the estimate. Orthodontal appliances sold first by a dental laboratory to a dentist, and subsequently sold again to the patient, illustrate duplication in the measure of output.

Historical estimates of output are converted from current year or nominal dollars to constant dollars and projections of 1995 output are based on constant 1977 prices.

[10] Data on employment by SIC category, shown in table 4, differ from those by economic growth sector shown in table 3 as follows:

Table 3:	Excludes State and local government hospitals Excludes 8042, Offices of optometrists Includes 074, Veterinary services
Table 4:	Includes State and local government hospitals Includes 8042, Offices of optometrists Excludes 074, Veterinary services

Excluded from the data shown in both tables are Federal hospital employees, as well as employees of publicly operated nursing homes, clinics, and other governmental health care facilities. These data also exclude self-employed workers.

[12] The number of nursing home users rose from about 300,000 in 1950 to 470,000 by 1960 and over 1,400,000 in 1980. A portion of this increase represented a substitution among different kinds of health care institutions. Beginning in the late 1950's after the introduction of psychotropic drugs, but predominantly in the late 1960's and early 1970's, many mental patients were transferred to nursing homes or board and care homes. The deinstitutionalization movement reflected prevailing views about the desirability of providing care in less restrictive settings, court orders, and cost savings to the States from placing patients in facilities where the Federal Government—via medicaid and Supplemental Security Income—would pay some or all of the cost. [30] Employment projections for the nine health industry categories of the National Industry-Occupational Matrix were derived from economic growth sectors 140–142 in a two-part procedure.

First, projected employment in SIC 074, veterinary services, was removed from projected private wage and salary employment in the economic growth sectors. Next, disaggregation to the nine matrix industries was accomplished using a time series regression analysis. The results were reviewed and adjusted according to analytical judgment.

Second, projections of State and local government hospital employment were added to the estimate of private hospital employment in SIC 806. No explicit adjustment was made for SIC 8042, Offices of optometrists.

Hospital employment under revised medicare payment schedules

A preliminary study of the employment effects of medicare payments based on Diagnosis Related Groups suggests that cost-cutting responses by hospitals will result in smaller, more highly skilled staff and a higher proportion of clerical to health care workers

EILEEN APPELBAUM AND CHERLYN SKROMME GRANROSE

In the face of declining employment in manufacturing, service sector industries such as health services are expected to offer expanded employment opportunities in the future. More than 900,000 jobs have been added in the health services industry since 1975, making it one of the largest industries in the U.S. economy. Moreover, the number of Americans over 65, who make the greatest use of health care services, is currently approaching 29 million and continues to grow.

Recently, however, the Federal Government has attempted to limit the rise in health care costs by instituting a prospective payment system based on Diagnosis Related Groups, or DRG's. Under the former system, reimbursement for hospital treatment covered by medicare at an acute care hospital[1] was based on the prevailing rates for hospital and physician care in the locality. Hospitals typically recovered the full cost of care for each patient.

Under the new system, payment is based on the average cost of patient care, with hospitals recovering more than the actual cost in some cases, and less in others. Reimbursements are made according to a fee schedule that mandates specific payments for each of 467 Diagnosis Related Groups. Payment to hospitals for inpatient care is assigned according to four criteria: a patient's principal diagnosis or surgical procedure, whether there is an important secondary diagnosis, the patient's age, and whether or not the patient was alive upon discharge. (An example of a Diagnosis Related Group is DRG 122: Circulatory disorders with acute myocardial infarction; without cardiovascular complications; patient discharged alive.) Each hospital's payment is adjusted for local wage levels.

The payment is expected to cover all costs except those related to staff education and capital expenditures. All direct medical education costs as well as indirect costs are reimbursed separately, as are capital expenses. Moreover, services provided on an outpatient basis or outside an acute care facility are currently exempted from DRG coverage. The DRG schedule is applied to inpatient services rendered to medicare beneficiaries. Therefore, the importance of medicare as a source of hospital revenue varies according to the size and complexity of the medicare caseload. This payment system provides an incentive to reduce costs within acute care hospitals because hospitals receiving medicare payments are permitted to retain any savings but must also absorb any expenses exceeding the scheduled payment rates.

Eileen Appelbaum is an associate professor of economics at Temple University, Philadelphia. Cherlyn Skromme Granrose is an assistant professor of human resource administration at the same university.

These attempts to limit the growth of health care costs have begun to affect employment opportunities in several important ways, including the number of jobs, hours of work, skill levels, and mix of occupations. This article is a preliminary report on the way in which human resource use in the hospital sector of the health service industry is responding to current efforts to contain expenditures. The following discussion briefly outlines the economic setting and related changes affecting hospitals, and then describes the strategies that have been adopted by certain Philadelphia hospitals to cope with this environment.

The changing environment

The cost of health care in the United States has risen steadily over the last few decades, increasing from 4.4 percent of gross national product in 1950 to 10 percent in 1984. Payments to hospitals have been the largest component of such expenditures, increasing from about 28 percent of the total in 1950 to just over 40 percent in 1980.[2] Payments from medicare, a Federal program established in 1965 to meet the costs of hospital care for elderly or disabled patients, currently amount to 38 percent of all hospital revenues.[3]

In an effort to slow the growth of medical costs and hold down public expenditures for health care, Congress passed legislation in October 1983 that established a medicare payment system based on DRG's. DRG's were phased in over a 3-year period beginning the following year. Between January and August 1984, 70 percent of community hospitals came under this pricing system.

Uncertain about the eventual effects of DRG's on revenues and anticipating a need to reduce costs across the board, hospitals with large medicare caseloads attempted to reduce admissions of less acutely ill patients and shorten hospital stays before the new system was implemented. As a result, the patient census declined sharply at some hospitals, but then recovered somewhat as hospitals became more familiar with the system. In addition, as described below, DRG's and changes in private insurance approaches to health care have encouraged the establishment of nonhospital treatment facilities. Younger or healthier patients may prefer these outpatient alternatives.

The effect of these developments on hospital utilization is reflected in aggregate data. Total admissions, which had already leveled off in 1982 and 1983 for reasons largely unrelated to DRG's, fell sharply—by 4 percent—in 1984. The average length of a hospital stay declined by 2 percent in 1983 and 5.1 percent in 1984.[4] For medicare patients, it declined by about 20 percent between 1983 and 1984, from 9.6 to 7.4 days.[5]

Cost containment measures adopted at many facilities slowed the growth in cost per case. Hospital expenses rose only 4.6 percent in 1984 compared with 10.2 percent in 1983, despite the fact that inflationary pressures on hospitals were virtually unchanged.[6] Medicare payments to hospitals increased 9 percent in the fiscal year ending June 1985 compared to an average of 19 percent in each of the 3 preceding fiscal years.[7]

Labor costs are the single largest budget item for hospitals, constituting over one-half of operating expenses in most instances.[8] Many of the cost-cutting strategies which hospitals have adopted are intended to effect savings in this area through reductions in employment or changes in staffing patterns. Thus, despite continued growth in employment in the health service sector, hospital employment turned down for the first time in 1984, with all of the decline occurring in general medical and surgical hospitals.[9] These are precisely the institutions which are subject to DRG's.

While the effects of DRG's on total hospital employment are reasonably clear, their effect on the mix of occupations and skills is uncertain. There are many possible strategies that hospitals might adopt to adjust to these cost containment measures, each with somewhat different implications for trends in health care employment. Our study focused on the strategies adopted by a number of hospitals located in Philadelphia and explored their human resource implications.

Data for this study were collected in three stages. First, a short, structured questionnaire was distributed to all administrators attending a meeting of the Philadelphia Hospital Personnel Society. This questionnaire asked respondents to classify their hospital's size, type, and specialization and to indicate their own administrative position. It also asked them to indicate for each of a list of occupations whether full-time, part-time, and contract employment was declining, static, or growing in their hospital. Thirteen completed responses were obtained at this meeting. Of the hospitals responding, 10 were private and 3 were public; 10 were teaching institutions and 3 were community hospitals. They ranged in size from 82 to 600 beds with an average size of 257 beds. All of the hospitals were nonprofit.

The second stage of data collection consisted of a series of 1½- to 2-hour personal interviews of seven of the hospital administrators who filled out the initial questionnaire. These interviews, conducted in August and September of 1985, focused on the general employment strategy of the hospital, any changes in strategy in response to DRG's, and the rationale behind adoption of these policies and practices. We also requested more precise estimates of the number or proportion of employees in each employment category added, deleted, or transferred since the implementation of DRG's. Hospitals selected for interviews were chosen to provide as much variation as possible. However, no attempt was made to obtain a representative sample and caution should be exercised in generalizing from these results.

A third aspect of data gathering consisted of using archival data to identify the broader changes in patient census and employment in all Philadelphia area hospitals. This enabled us to place the responses of interviewees into a more general context.

Effects of DRG's uneven

Just as their counterparts elsewhere, Philadelphia area hospitals began preparing for the implementation of DRG's even before the authorizing legislation had been passed. In the view of some of the hospital administrators interviewed, the initial response at many institutions was an overreaction to the prospect of a fixed fee schedule. With 2 years of experience since passage of the legislation, the administrators believed that reactions had moderated, although the extent and difficulty of required adjustment varied widely among hospitals.

An overview of pertinent hospital operations in the Philadelphia area can provide useful perspective for interpreting these and other responses to our study. Admissions for the 90 Philadelphia area hospitals (including those in the New Jersey suburbs) declined nominally from 325,966 in late 1982 to 325,733 in late 1983, then rose to 326,943 by 1984.[10] Philadelphia's experience in this respect differs sharply from that of the Nation as a whole, which experienced an unprecedented decline in admissions in 1984. Reasons for this difference include the relatively high proportion of elderly people in the Philadelphia area, the substantial number of referrals from outside the area to major medical centers in Philadelphia, and the below-average enrollments of health maintenance organizations (HMO's) in the area.

While admissions remained essentially stable in Philadelphia, hospitals stays were shortened. Length of stay in acute care hospitals declined steadily from 8.8 days at the end of 1982 to 7.5 days in 1984.[11] The combination of stable admissions and declining length of stay enabled Philadelphia hospitals to earn record income while containing costs. Of the 60 hospitals in Philadelphia and its Pennsylvania suburbs, all but three were in the black for the fiscal year ending June 30, 1985. The five hospitals with the highest net income included a children's hospital, a community hospital, and three teaching hospitals. Taken together, the 60 Philadelphia hospitals had income exceeding $165 million on revenue of more than $3 billion.[12]

While DRG's provide incentives to all hospitals to decrease length of hospital stay and to compensate for the decrease in bed occupancy rates by increasing the volume of admissions, the effects are very uneven across institutions. The employment impact depends, in part, on the extent to which the hospital is affected by DRG's and the size of the hospital's medicare caseload. DRG's currently do not apply to specialty hospitals, which do not provide acute care. These include psychiatric institutions, drug and alcohol treatment centers, and physical rehabilitation facilities. Children's hospitals are also waivered under present regulations. Cost containment pressures thus are far less severe in these institutions than in acute care hospitals. Nevertheless, specialty hospitals are responding to a number of pressures for change. These include the expectation that coverage by DRG's will eventually be extended to them, incentives from private health insurers to reduce costs, greater acceptance by patients of less expensive outpatient care, and increased competition from freestanding, specialized facilities established by acute care hospitals to avoid DRG coverage.

One speciality hospital we examined had initiated a study of how it should respond to the impact of DRG's. As a result of what it had learned by the time of the interview, this hospital had taken steps to become an outpatient surgery facility. It had arranged for an acute care hospital to take its more seriously ill patients and had already converted an entire inpatient floor to day surgery. Because of these measures and the increasingly competitive environment in which the hospital operates, the inpatient census at this facility was at 40-percent occupancy in 1985, compared with 56 percent a year earlier. However, the outpatient service increased over the same period: outpatient visits increased 8.4 percent between fiscal years 1984 and 1985 while outpatient surgical procedures increased 19.7 percent over the same period.

In this hospital, the effect on employment levels had been minimal, although employees had been shifted from inpatient to outpatient care. The nursing staff remained stable between 1983 and 1985, with 82 registered nurses (of whom 76 work full time), 14 nurse's aides, and no licensed practical nurses. The number of ward clerks in patient care units decreased from 16 to 12 over that period. However, total clerical employment also remained stable at about 41, because three positions for coder-abstracters (currently filled by temporary workers) have been added in the medical records department. The number of people employed as medical technicians, secretaries, and administrators remained unchanged.

The hospital anticipated reduced labor requirements in areas such as dietary, housekeeping, and maintenance services as the shift from inpatient to outpatient care proceeds, but this had not occurred at the time of the interview. Employment in the service unit, which numbered about 125 in 1983, had been reduced by two full-time-equivalent positions, and there had been a moderate shift toward more part-time staff in this area. The only employment growth anticipated by this hospital was in the medical records department, which at the time was burdened by the increase in the number of people seen as outpatients. A systems analyst position was expected to be added and two or three clerical positions were to be made permanent when an evaluation of medical records operations was completed.

Separate reimbursement for medical education expenses under the DRG payment system has had differential effects on the revenues of teaching and nonteaching hospitals. Payments for direct education costs are based on actual cost, while those for indirect costs depend on the size of house staff, the number of beds, and the total payment from medicare. It has been estimated that adjustments for indirect teaching costs increase the payments to teaching hospitals with one or more interns or residents for every four beds by an average of 53 percent, while combined adjustments for direct and indirect medical education costs approximately double the reimbursement to a teaching hospital compared with the DRG payment per case to a nonteaching hospital.[13] In part, these increased payments are intended by medicare to compensate teaching hospitals for the greater severity of the illnesses they treat and for the free care they provide to patients with no medical coverage, although other hospitals with acutely ill patients or which provide free medical services receive no such compensation. The result of this payment system has been to encourage teaching hospitals to categorize expenditures as direct educational costs whenever possible and to shield their revenues from the effects of DRG's.

The administrator of one very large teaching hospital stated that DRG's were having negligible effects on admissions, length of stay, and occupancy. This hospital's 1984 occupancy rate exceeded 79 percent, compared with an average of 73.4 percent for other medical school hospitals and 69.3 percent for other acute care hospitals in the region.[14] Not surprisingly, DRG's had not affected employment levels at this hospital at the time of our study and were viewed by the respondent as only one among many factors affecting decisions about human resource use. However, a second medical school hospital administrator stated that his institution was already initiating changes to increase volume of admissions and reduce length of stay in anticipation of cutbacks in medicare payments for educational costs. (At the time of our interview, the Advisory Council on Medicare had already proposed to Congress that these payments be terminated by 1987.)

In general, the hospitals with revenues most adversely affected by the DRG payment system were acute care community hospitals, especially those serving an elderly or poor population. The reasons for this are implicit in the type of diagnosis-based, per-case reimbursement system which medicare has adopted. The DRG system uses limited information in assigning a patient to one of its 467 categories. In particular, it largely ignores the severity of the illness in making an assignment and it ignores socioeconomic characteristics of the patient that may affect the number of complications and thus the cost of treatment. In addition, no allowance is made under DRG's for free medical care provided to those unable to pay for services.

A study conducted at Johns Hopkins found that teaching status of a hospital did not necessarily predict the severity of illness of its patient population. Some nonteaching community hospitals have severe case mixes despite their low resident-to-bed ratio. These hospitals receive little reimbursement from medicare for educational costs to offset their higher than average treatment costs.[15] The greatest pressures for cost containment, and the greatest challenges to hospitals that want to maintain the quality of, and access to, their services, occur in this category.

The hospital in which we observed the greatest effect of DRG's was a community hospital that had responded to what it termed "the Federal mandate for quality health care" in the 1960's and 1970's by gearing up to provide care for the poor and the aged. At the time of the study, 60 percent of its patients were on medicare. The hospital had responded to the medicare revenue cuts that accompanied the implementation of DRG's with a concerted cost containment effort. Most obvious was the reduction in average length of patient stay from 10 days to 7.2 days between 1983 and 1985. In contrast, the average length of stay at acute care hospitals in the Philadelphia area had fallen from 8.8 days to 7.5 days over the same period.[16] In this hospital's view, the longer average length of stay for its patients in 1983 was due to the fact that recovery takes longer when the patient population is older and poorer, not to inefficiencies in the hospital's operations. This contrasts with medicare's underlying assumption that all cost differences in treating patients in the same Diagnosis Related Group result from differences in efficiency among hospitals. Under extreme pressure to reduce costs, this hospital had brought its average length of stay in line with the Philadelphia average. As a result, the hospital's patient census had declined more than 15 percent since 1983, yielding its 1985 occupancy rate of 62 percent.

Anticipating the implementation of DRG's, in 1983 this hospital obtained a 2-year grant to study the effects of DRG's on the lives of the elderly. Preliminary results suggested that while there had been no increase in medical risk, more than 54 percent of the 200 patients interviewed in the first year indicated a fear that they were returning home too early in their recovery. The hospital was concerned about the social and psychological stress to which these elderly patients are being exposed, the adequacy of care available to elderly people living alone, and the stress placed on relatives asked to care for these patients.

Strategies for coping with DRG's

Strategies to adjust to the changing financial environment can be divided into three categories—strategies for "beating the system," marketing strategies, and human resource strategies. Strategies in the first two categories also have consequences for human resource use, even though these practices are not adopted specifically as human resource strategies.

"Beating the system." The uneven effects of DRG's on hospitals and the complex economic incentives the payment system provides have led hospitals to adopt a variety of strategies for maximizing income under the new rules. These include such obvious tactics as identifying combinations of patient diagnoses that maximize payments and choosing the principal diagnosis or procedure carefully to achieve the same end. These practices were aggressively pursued at all of the hospitals we observed. Training was provided for personnel ranging from doctors to medical records clerks in assigning diagnoses to the DRG category that yields the most revenue for the hospital. This practice

may have contributed to the increase in recent years in the case mix index—a national measure of the severity of patient illnesses—which is rising much more rapidly than expected,[17] although acuity levels at hospitals are increasing as less ill patients are treated at outpatient, rehabilitation, or other facilities. In addition, separate payments by medicare for capital expenses favor the use of capital intensive techniques. They also encourage hospitals to experiment with equipment leasing and innovative accounting procedures to qualify for reimbursement for capital expenditures.

Partly as a result of the favored status afforded capital intensive techniques under DRG's, some hospitals have continued to add employees in high technology specialties. Four of the hospitals at which we interviewed cited recent or anticipated employment growth in radiology, ultrasound, magnetic resonance, CAT-scan, nuclear medicine, and nuclear studies in cardiology. Between 5 and 10 technician or technologist positions had been added at these hospitals in 1984 and similar employment growth was anticipated for 1985. Competition for individuals highly credentialed in these areas is keen, and some hospitals had had to offer higher starting wages in order to recruit such workers, and to renegotiate contracts in order to retain them. One hospital reported retraining existing personnel to fill some of these positions.

Employment growth in technical specialties was far outpaced by the number of new clerical and administrative positions added in medical records, billing, and related departments in response to DRG's. All of the hospitals we observed had increased employment in these areas. Administering DRG's to yield the highest payment for each patient had caused one hospital at which there were substantial cutbacks in patient care personnel to increase the numbers of medical record administrators, technicians, and clerks; to add three programmers; and to employ an additional admitting officer, financial analyst, manager of financial planning, and several accountants. Another hospital which had reduced the number of licensed practical nurses and nurse's aides by more than 30 positions between 1983 and 1985 reported large employment increases in billing, data processing, medical records, and utilization review over the same period. The billing department alone had grown from 40 to 60 people, while the number of coders in medical records rose from 17 to 25. The hospital also reported having retrained clerical employees to choose the best diagnosis financially while conforming to regulations.

Marketing strategies. Marketing strategies at the hospitals where we interviewed were two-pronged. The hospitals had made significant efforts to increase admissions. They had also developed marketing strategies that focused on procedures, populations, and services for which DRG limits are less constraining.

To increase admissions, and to target the populations they wish to admit, hospitals throughout the country are competing for patients through direct marketing and advertising activities. The hospitals we visited were making increased use of marketing consultants, and some institutions had hired or were planning to hire marketing directors.

Hospitals are also courting physicians. Four of the acute care hospitals we studied reported that they were increasing the number of attending physicians. Some were encouraging attending doctors to form health maintenance organizations. More often, hospitals today are encouraging doctors to form professional associations to provide specialized services such as radiology within the hospital on a private, for-profit contract basis. This practice appeared to be widespread in the two teaching hospitals we observed, extending beyond medical imaging and anaesthesiology to include such unlikely specialties as dermatology. Other hospitals had also developed such subcontract arrangements or were discussing them for medical specialties as diverse as biomedical services, urology, and the short procedures unit, in which outpatient surgery is conducted. In return, the hospitals expected doctors with whom they have such arrangements to admit more patients.

To escape the constraints of DRG's, and in response to private health insurance incentives for avoiding inpatient care as well, hospitals are increasing the provision of services not covered by these regulations. The most common strategy is to enlarge the short procedures unit and to shift from inpatient to outpatient services. In some of our study cases, entire floors or units had been shut down and the personnel reassigned or released. Some of these hospitals were establishing new, independent units to provide psychiatric, physical rehabilitation, or drug and alcohol treatment outside the acute care facility. Such units are exempted from DRG coverage. Home health care is another new service with which hospitals were experimenting.

Another strategy used by hospitals to increase revenues is to attract specific types of patients who will make relatively less use of the hospitals' resources than other patients within the same DRG. A recent study confirms the fact that patients with the same diagnosis may be more or less acutely ill. In a related study comparing reimbursement rates with the actual extent or severity of illness, researchers found both substantial overpayments and underpayments. Some institutions received payments that were as much as 59 percent too high and others received 25 percent too little in relation to the burden of illness and the actual costs of treating their patients.[18]

Hospitals prefer patients who are younger or are in sociodemographic groups that are likely to have fewer complications and shorter hospital stays. They also prefer patients with private insurance coverage which does not rely on DRG-type reimbursement policies. In addition, hospitals have identified those diseases which are profitable for them under the DRG system, and they seek to increase admissions of patients with these ailments. Treating the right type of patient increases the "contribution margin" to the hospital, raising the difference between what hospitals are paid for treating the patient and the actual variable cost of the care. A leading management consulting firm has prepared what it labels "a survival guide for the hospital industry," in which hospitals are advised that they must determine their "winners" and "losers"—that is, those DRG's that are most and least profitable; identify the types of patients that provide the greatest contribution margin and target them; and decide which physicians should be encouraged to use hospital resources.[19]

For persons concerned about the wide availability of quality health care, the benefits of marketing strategies are not always clear. One hospital administrator cited unproductive competition with suburban hospitals for attending physicians and patient admissions in categories where costs are below average. A respondent at a rehabilitation hospital pointed to a shift in workers and other resources from an older facility in a lower income, black community to a newer center in a middle income, white neighborhood. While the hospitals at which we interviewed, especially the community hospitals, expressed a continuing commitment to providing medical care to those who need it, the practice of using marketing strategies to attract a preferred patient population raises troubling questions about access for persons requiring hospital stays that exceed the average or for those who lack medical insurance coverage.

All of these marketing strategies have implications for human resource use. This was most evident at a speciality hospital we observed where a new administration decided last January to take steps to run the hospital more like a business. In addition to 13 positions, including 10 office and clerical jobs that had already been added in 1984, 35 new positions were approved for 1985. The new positions included a director of development, an insurance liaison person, an admissions liaison person, and a coordinator to test-market potential products.

In general, we found that the medical records department had grown at each of the hospitals we visited. Greater use of outpatient facilities and short procedures units has increased the number of patient visits, and hence the number of bills that must be sent to patients. At one medium-sized hospital, not only had there been a shift from inpatient to outpatient care but the hospital's general practice department had become part of a health maintenance organization. The resulting increase in billing requirements had led to a marked increase in employment in the billing department.

The establishment of freestanding units to provide specialized treatment outside the hospital and the subcontracting of hospital services to professional associations of doctors had affected the number of workers officially counted on hospital payrolls, although the effect on actual employment was less clear. Doctors in these situations negotiated with hospitals over the sharing of expenses and over whether the staff in their facilities would be employees of the doctors or of the hospital. We found that where hospitals were not unionized, workers were often considered employees of the doctors. The hospital would prepare the payroll and send out paychecks, but the workers were not carried on the hospital's employment rolls.

Labor force strategies. Responding to DRG's through the use of human resource strategies, Philadelphia hospitals were attempting to reduce labor costs while avoiding widespread layoffs. Layoffs had occurred at some hospitals, but most of the reported reductions in staff at the hospitals we visited had been accomplished through attrition and incentives for early retirement. One hospital, adjusting to a decline in its occupancy rate of 20 percentage points as a result of a reduction in average length of stay from 10 to 7 days, had found it necessary to reduce its staff by 111 positions. First, retirement incentives were made available at all vertical levels of the employment structure, although the hospital found that this option appealed mainly to less skilled, lower paid workers. As a result, 31 people retired early. The second stage of the reduction was accomplished by laying off workers over a 5-month period in 1985. Such workers were given preemptive rights to return—that is, they were hired back as others left voluntarily and jobs for which they were qualified opened up. By the end of 1985, only 9 people remained on the layoff list, the rest having been rehired in the course of normal turnover.

While only two hospitals had found it necessary to lay workers off, all of the hospital administrators interviewed reported having used attrition to achieve targeted reductions in staff. Selective cutbacks through attrition had been accomplished at every employment level including administration, although most reductions had occurred among less skilled nursing staff. If targets were not met by the end of the fiscal year (June 1986), some hospitals anticipated using layoffs to reach employment goals.

Attrition is a viable strategy for hospitals because of the high turnover that characterizes many of them. One large hospital we visited, with approximately 3,200 employees, reported turnover of about 17 percent in fiscal 1984 and 23 percent in fiscal 1985. This occasioned the hiring of about 950 new workers in 1984, and about 750 in 1985. Thus, there had been extensive hiring at this hospital despite a reduction in staff of more than 100 positions during fiscal 1985. Several medium-sized hospitals reported reductions in staff through attrition of up to 100 positions over the preceding 2 fiscal years.

Despite the use of retirement incentives, attrition, and occasional layoffs, hospitals were not planning across-the-board reductions in staff. Most of the hospitals we visited had conducted detailed studies of staffing needs and had set employment targets for each department, including increases in some areas and reductions in others. This had involved considerable shifting of employees among departments. The closing of entire inpatient nursing floors and the scaling down of some programs at the hospitals had been accompanied by expansion of short procedures units and other outpatient facilities.

Nurses and ward clerks had been shifted from inpatient to outpatient care. One hospital reported that about 70 percent of those displaced from inpatient care had been reabsorbed in this way. Another hospital had found that shifting nurses from the nursing floor to day surgery required a new orientation and specialized training; staff nurses had been given the option of getting the training in order to retain their jobs. The most unusual reassignment we observed occurred at a hospital where requirements for less skilled nurses were declining while the need for clerical workers was increasing. The administration had given licensed practical nurses the option of shifting to clerical work. Several nurses had taken advantage of the offer and had made the change quite successfully.

Engineering and maintenance requirements remained virtually unchanged as hospitals adjusted to DRG's, and housekeeping services experienced about a 10-percent decline in employment. However, several hospitals reported that they had not filled all of the positions in these departments lost through attrition.

Only food service requirements had consistently and markedly declined as a result of the decline in inpatient census and the increase in outpatient services. One hospital reported making shifts in the assignment of nonunion employees in this area, but not for those who were unionized.

Hospitals are also adopting a variety of human resource strategies that increase their flexibility in using their employees. One notable development, emphasized by all but one of the hospitals we observed, is increased reliance on registered nurses, especially those with Bachelor of Science in Nursing degrees, and reduced employment of nurse's aides and licensed practical nurses. Reducing the length of hospital stays during the recuperative period means that patients who are in hospitals are more acutely ill, with the result that more skilled nursing care is required.

Most of the hospital administrators we interviewed believed that it is inefficient to continue to use licensed practical nurses and nurse's aides, who are limited in the tasks they can perform. One hospital had already eliminated all licensed practical nurses. Only one community hospital administrator, sorely pressed by DRG's, took the position that registered nurses should be used to provide professional nursing services only, while auxiliary services should be provided by lower paid licensed practical nurses and aides.

The result is that many of the hospitals we visited were maintaining employment levels for registered nurses and grauduate nurses (and some were even recruiting in this area) because such nurses can provide the entire range of nursing services. At the same time, there had been cutbacks in the less skilled nursing positions. One hospital reported having laid off 17 workers in July 1984 and the same number the following October. Most of those laid off were nurse's aides. Cutbacks at other hospitals had been less extreme, but several reported no new hiring of aides or licensed practical nurses within the last 6 months of the interview, and no future plans to hire them.

Some hospitals reported having instituted, or considered establishing, internal labor pools to increase flexibility in assigning workers to departments where they are needed. Such a strategy usually is intended to avoid layoffs and increased use of part-time workers. The underlying premise, viewed as still unproven by most of the administrators we interviewed, is that one department is busy while another has down time. The argument is that down time can be reduced and productivity increased by assigning people of like educational attainment to a labor pool, rather than to a department, and cross training them to do a variety of jobs. Workers can then be assigned from the pool to a department as needed. Several hospitals had begun (or were considering) using a labor pool to staff less skilled jobs in housekeeping, grounds, maintenance, food service, and transport.

A few hospitals were coping with fluctuations in admissions and swings in patient census by establishing nursing pools. Nurses who do not want, cannot find, or are not needed by the hospital for full-time employment are carried on the rolls of the hospital's nursing pool and called in to work by the day. One medium-sized hospital with 155 registered nurses and graduate nurses on the floor, another 15 in education, administration and supervision, and about 25 licensed practical nurses and 35 aides, had a nursing pool of about 80, of whom no more than 30 were actively contacted by the hospital on an average day. The people in this pool were not reported as hospital employees in employment statistics kept by the institution. They were paid a straight wage for the days they worked and received no fringe benefits. They became eligible for a pension if they worked more than 1,000 hours in any year, so the hospital attempted to keep their employment under this level.

Another hospital, unable to fully employ all of its nurses in the face of the decline in its patient census, operated a different type of nursing pool in which everyone is a hospital employee and is guaranteed work every day but not necessarily at the hospital. The hospital operated the nursing pool as a temporary help service, sending the nurses it did not require on any given day out to nursing homes or other facilities, as needed. This pool had, in fact, become a "profit center" for the hospital.

Several hospitals had small clerical pools as well. At one, a pool of five clerical workers was treated as belonging to the employee relations department. These workers, who were viewed as permanent employees of the hospital, were called in as needed and charged to whatever department used them. The hospital treated them as part-time workers.

Several alternative strategies for reducing labor costs which we expected to find were notable by their absence. In general, the hospitals we observed had made only limited use of part-time employment to increase flexibility in work assignments. Perhaps 10 percent of employees at these hospitals work part time, usually in food service and in weekend nursing services. One hospital had gone from two full-time shifts in food service to one full-time and one part-time shift. Other hospitals reported that about a third of their food service workers were part time.

Weekend nursing services have traditionally employed part time registered nurses, licensed practical nurses, and aides who wanted those hours. Today, fewer patients remain in the hospital on weekends. But hospitals are providing additional outpatient services on weekends and evenings in order to meet increased competition from freestanding facilities. One hospital we visited had begun providing physical therapy and respiratory therapy at those hours.

In recent years, hospitals have also begun making part-time work available to physical therapists, who are currently in short supply, in order to make the jobs attractive. Apparently, a substantial number of physical therapists do not want full-time work and are able, in the current market, to command the hours they desire. The net effect of this trend on part-time employment among the hospitals we visited had been small.

None of the seven hospitals we observed had increased the responsibilities of lower paid workers in order to economize on the use of more highly skilled and higher paid staff. On the contrary, they sought to hire the most highly credentialed workers available. This was especially evident in nursing, where the proportion of registered nurses was increasing and the nurses were being asked to perform the entire spectrum of nursing services, but it applied to technicians and therapists as well. Hospital administrators reported that greater cost savings are realized as a result of the flexibility provided by a smaller staff of highly skilled workers than through an increase in the proportion and responsibilities of lower paid workers.

Hospitals do make use of temporary workers, mainly in nursing services and, to a lesser extent, in clerical work. But the hospitals we observed made only occasional use of temporary help service agencies. Instead, they preferred to contract with individuals for these services, forming their own internal pools of temporary workers. Often, the workers in these pools previously held full-time positions at the hospitals, but for personal reasons came to prefer fewer hours. Other workers in the pools may desire full-time jobs at a particular hospital and view the pool as a way of getting preferential treatment should an opening arise. Sometimes the pool was established as an alternative to laying off workers entirely.

In general, the hospitals in our survey did very little contracting out of services. None of the hospitals we visited contracted out services such as food service, housekeeping, groundskeeping, or maintenance. One hospital was contracting out electrical services at the time of the interview but planned to hire its own electrician shortly. Another hospital was contracting out food service in the employee and visitor cafeterias, but not its inpatient food service. The hospital administrators we interviewed rejected the use of temporary help agencies or of contract services because they believed there are hidden or long-run costs associated with the use of workers who are not their own employees. Because pay at these hospitals rose during the 1970's, the administrators no longer viewed their institutions as employers of last resort. Quality of employees at every level was higher by the mid 1980's than it had been 10 or 15 years earlier, and respondent hospitals thus were reluctant to surrender control over this employment to outside agencies.

Implications for employment outlook

According to our study, implementation of a prospective payment system by medicare had an immediate effect on employment in acute care community hospitals most directly affected by DRG's. Cutbacks in employment in these facilities have largely been in patient care occupations. They are associated with the reduction in length of hospital stay and with the incentives for cost containment implicit in a system which allows hospitals to retain the difference between scheduled prospective payments and the actual costs of providing health care services.

Employment growth was centered in occupations associated with hospital efforts to prosper under DRG's by increasing admissions, targeting a preferred patient population, coding patient diagnoses so they are most financially remunerative, increasing the use of capital intensive procedures for which payment is more easily obtained, and establishing or expanding treatment facilities and services that are not yet covered by the payment system. In our interviews, we observed only small changes in employment in the specialty and teaching hospitals, which are less severely constrained by DRG regulations. However, all but one of these hospitals were expecting that future regulatory changes would directly affect them. They reported that they were exploring the use of (and, in one instance, were actively utilizing) the marketing and human resource strategies that acute care community hospitals had adopted during the 2 years preceding our study.

In direct patient care occupations, the overall employment of registered nurses and graduate nurses was stable, although there had been a definite shift in location of a substantial proportion of these jobs to short procedures units, outpatient services, offsite specialty units, or freestanding facilities in more prosperous communities. The employment of licensed practical nurses and nurse's aides was declining, while a few specific technical specialties benefiting from DRG regulations were experiencing small increases. Physical therapists, who benefit from the exemption from DRG coverage of rehabilitation facilities, were also facing a high demand for their services.

In support service occupations, those concerned with the maintenance of physical facilities had experienced stable employment, though hiring was limited to replacement only and was sometimes sluggish. Support service occupations that depend on the hospital's inpatient census, such as food service, housekeeping, and patient transport, were declining. Food service occupations were the hardest hit, and some workers in this area who did retain their jobs had had their hours reduced.

The largest increases had occurred in administrative and administrative support occupations. We observed small increases in positions for upper level administrators with skills in marketing, product development, finance, and DRG administration. These had been filled through outside hiring. Larger increases were reported in clerical occupations in billing and medical records, especially in occupations related to DRG reporting requirements. These positions had sometimes been filled through outside hiring. Often, however, they had been staffed through transfers within the hospital from departments experiencing cutbacks.

Our limited data suggest that the major impact of the decline in hospital employment is being felt in the less skilled, traditionally female occupations such as licensed practical nurses, nurse's aides, and food service workers. A case study of hospitals such as this does not provide information on whether workers displaced from hospital employment are finding jobs in nursing homes, home health services, or other health service facilities. Even if this is the case, however, displaced workers are unlikely to find jobs that pay as well or provide as many hours of work as those they previously held. Hospital administrators with contracts with home health care agencies or who were developing this service themselves reported that the position of home health care aide is becoming more skilled than that of a nurse's aide in a hospital setting because there is less direct supervision. Yet the job pays about $3.35 to $5 an hour, about half the hospital pay scale for nurse's aides, and the hours, which are not dependable, may vary from 10 to 40 a week.

Our findings also suggest that while high turnover and the continued need to fill a few specialized positions precludes a hiring freeze at hospitals, very little net growth in employment in the hospital component of the health services sector can be anticipated in the next few years. This is especially true of acute care institutions. We also noted a shift in the composition of the nursing staff at hospitals toward graduate and registered nurses, whose numbers were stable or growing slightly. This appears to be the result of both the thrust within nursing for professionalization and the desire of hospitals to operate with a nursing staff that is smaller overall but more highly skilled and flexible. The preference for more highly skilled workers was apparent as well in other occupations at the hospitals we observed. These hospitals were continuing to recruit employees with training in specialized technical procedures and those with traditional business specialties such as marketing and finance.

Our method addresses the proximate effects of DRG's on hospital employment. However, it does not allow an analysis of overall employment effects in health services as full adjustment to the new payment plan is undertaken. Many questions remain. These include whether displaced licensed practical nurses and nurse's aides are finding alternative employment in nursing homes and home health care; whether the stresses on families caring for elderly patients at home are creating unrecognized increases in the demand for psychological and social work services; and what the effect will be on the demand for health services provided outside of hospital facilities. However, our case study of a small number of hospitals strongly suggests that DRG's are triggering changes in hospital employment and in the delivery of medical care that are having major spillover effects elsewhere in the health services sector and, perhaps, in the larger economy. □

[1] For purposes of program administration, an "acute care hospital" is defined by exception; that is, a facility is considered an acute care hospital unless it falls within a category specifically excluded from the program by law, such as an alcohol rehabilitation center. However, the term may be approximated by the American Hospital Association's definition of "community hospitals": Non-Federal, short-term general and other special hospitals, excluding hospital units of institutions, whose facilities and services are available to the public. Major Agreements Expiring Next Month

This list of selected collective bargaining agreements expiring in September is based on information collected by the Bureau's Office of Wages and Industrial Relations. The list includes agreements covering 1,000 workers or more. Private industry is arranged in order of Standard Industrial Classification.

Industry or activity	Employer and location	Labor organization[1]	Number of workers
Private			
Construction	Northeastern States Boilermakers Employers (Interstate)	Boilermakers	1,500
	Western States Field Construction agreement (Interstate)	Boilermakers	5,300
	National Electrical Contractors Association, South Florida Chapter (Florida)	Electrical Workers (IBEW)	1,150
Food products	A.E. Staley Mfg. Co. (Decatur, IL)	Industrial Workers	1,300
	Fluid milk and ice cream companies (California)	Teamsters (Ind.)	1,200
Textiles	Textile dyeing, printing, and finishing companies (Interstate)	Clothing and Textile Workers	3,400
Paper	Federal Paper Board Co., Inc. (Riegelwood, NC)	Paperworkers	1,200
Chemicals	Hercules Inc. (Radford, VA)	Oil, Chemical and Atomic Workers	2,200
Primary metals	American Steel Foundries (Inierstate)	Steelworkers	1,000
	CF&I Steel Corp. (Pueblo, CO)	Steelworkers	1,600
	Weirton Steel Corp. (West Virginia)	Independent Steelworkers Union (Ind.)	8,000
	Universal-Cyclops, Specialty Steel Division (Pennsylvania)	Steelworkers	1,100
	Atlantic Steel Co. (Atlanta, GA)	Steelworkers	1,000
	Interlake Inc. (Riverdale, IL)	Steelworkers	1,200
	Al Tech Specialty Steel Corp. (New York)	Steelworkers	1,750
Machinery	Dresser Industries Inc., Dresser Clark Division (Olean, NY)	Steelworkers	1,400
	Lufkin Industries Inc. (Lufkin, TX)	Various unions	1,800
	Rheem Manufacturing Co. (Fort Smith, AR)	Steelworkers	1,200
Electrical products	Whirlpool Corp. (Fort Smith, AR)	Industrial Workers	3,500
	Amana Refrigeration, Inc. (Amana, IA)	Machinists	1,500
	Magic Chef, Inc. (Cleveland, TN)	Molders	1,000
Transportation equipment	General American Transportation Corp. (Interstate)	Steelworkers	1,000
	Borg-Warner Corp., Warner Gear Division (Muncie, IN)	Auto workers	1,600
Water transportation	New York Shipping Association (Interstate)	Longshoremen's Association	8,500
	Philadelphia Marine Trade Association (Pennsylvania)	Longshoremen's Association	2,250
	Steamship Trade Association of Baltimore (Maryland)	Longshoremen's Association	4,500
	Hampton Roads Maritime Association (Virginia)	Longshoremen's Association	2,500
	New Orleans Steamship Association (Louisiana)	Longshoremen's Association	3,200
	West Gulf Maritime Association (Texas and Louisiana)	Longshoremen's Association	5,000
	South Atlantic Employers Negotiating Committee (North Carolina and Florida)	Longshoremen's Association	3,250
	Mobile Steamship Association (Alabama)	Longshoremen's Association	1,000
	Southwest Florida Employers Association (Florida)	Longshoremen's Association	1,100
Air transportation	Republic Airlines, mechanics, related personnel, stock clerks (Interstate)	Machinists	2,500
Utilities	Consumer Power Co. (Jackson, MI)	Utility Workers	4,700
Retail trade	Waldbaum, Food-A-Rama, and three others (New York, NY)	Retail, Wholesale, and Department Store	18,000
	Giant Food Stores (Washington, DC)	Food and Commercial Workers	7,000
	Safeway Food Stores (Washington, DC)	Food and Commercial Workers	5,000
	Giant Food Stores (Baltimore, MD)	Food and Commercial Workers	3,000
	Safeway Food Stores (Baltimore, MD)	Food and Commercial Workers	1,400
Real estate	Building Managers Association (Chicago, IL)	Service Employees	6,000
	Apartment Owners Advisory Council (Westchester, NY)	Service Employees	3,500

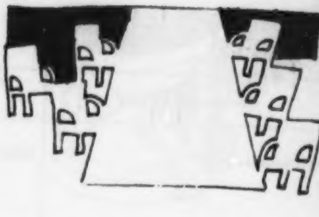
A note on communications

The *Monthly Labor Review* welcomes communications that supplement, challenge, or expand on research published in its pages. To be considered for publication, communications should be factual and analytical, not polemical in tone. Communications should be addressed to the Editor-in-Chief, *Monthly Labor Review*, Bureau of Labor Statistics, U.S. Department of Labor, Washington, D.C. 20212.

Developments in Industrial Relations



More steel settlements

The third settlement in the round of bargaining in the steel industry occurred when Bethlehem Steel Corp. and the United Steelworkers agreed on a 37-month contract for 30,000 employees. Reflecting the breakup of the major companies' united bargaining front and the union's recognition of the variations in the competitive problems facing the individual companies, Bethlehem's terms varied from the leadoff LTV Steel and National Steel accords. (See *Monthly Labor Review*, June 1986, pp. 45–46.)

The Bethlehem contract, which the workers approved by a vote of 11,600 to 8,369, calls for a cut in compensation totaling $1.97 an hour. According to the union, this reduces average hourly labor costs to between $22.50 and $23. The wage portion of compensation was cut 8.1 percent, or an average of 98.6 cents an hour.

As at LTV Steel, the settlement provides for a plan under which employees' wage and benefit sacrifices will be repaid in cash or shares of a new issue of dividend-bearing stock. Retirees and employees will receive annual payments from an allocation equal to 10 percent of profits up to $100 million and 20 percent of any excess. If this is not enough to offset the employees' sacrifices, the balance will be in shares of the stock.

As in the earlier accords, the Bethlehem settlement establishes a gain-sharing approach permitting local unions and management to develop plans for distributing cash to employees based on one or more of the following:

- tons of steel shipped;
- work hours per ton;
- quality of product; and
- reductions in nonlabor costs attributable to employee efforts or initiative.

The plans may include inducements—such as improved early retirement benefits and severance payments—in exchange for negotiated reductions in the work force, but Bethlehem is not permitted to contract out any work that had been performed by departing employees.

Among the cost-reducing contract changes accepted by the union were suspension of the provision for automatic quarterly cost-of-living pay adjustments, elimination of three paid holidays, time and one-quarter premium pay for Sunday work instead of time and one-half, and exclusion of overtime, Sunday premium, and shift premiums from calculations of vacation pay (unlike LTV Steel, the duration of vacations was not reduced).

Utility contracts

In Massachusetts, members of the Utility Workers Union ended a 1-month strike against Boston Edison Co. after ratifying 4-year contracts. Terms, which were similar for the three units of workers, included pay increases of 5 percent in the first year, 4.75 percent in the second and third years, and 4.5 percent in the final year. The shift differential also was raised by 5 cents an hour in each year, bringing it to 70 cents.

The pension plan was revised to permit 30-year employees to retire at age 60 at unreduced benefit rates (previously, the age requirement was 62). The plan also was revised to permit immediate retirement for 15-year employees who become disabled and are not able to perform the duties of their job or a similar job. If the company doctor and the employee's doctor are unable to agree on the extent of the disability, the decision would be made by a specialist recommended by the American Medical Association. Previously, such rulings were made by a review board, which required 100 percent disability. In another change, if an employee with at least 10 years of service dies, the surviving spouse will be entitled to a survivorship benefit (previously, the minimum requirement was 20 years of service).

A major concern was resolved when the parties agreed to establish a joint safety committee. Its first task is to oversee installation of a fire sprinkler system and removal of asbestos from the building where about 25 percent of the 2,800 employees work.

Other contract changes included doubling of accidental death and dismemberment insurance coverage to $200,000; 5-year pay rate retention for disabled employees demoted to lower paying jobs because of inability to perform current duties; a switch to a health insurance plan containing various requirements designed to contain premium cost increases;

"Developments in Industrial Relations" is prepared by George Ruben of the Division of Developments in Labor-Management Relations, Bureau of Labor Statistics, and is largely based on information from secondary sources.

and extension to clerical employees of grievance and arbitration procedures for resolving disputes over contracting out of work.

In the Washington, DC, area, 1,800 employees were covered by a 3-year agreement between the Washington Gas Light Co. and the International Gas Workers Union and the Office and Professional Employees. The settlement ended a 3-week strike, the first since a 17-day stoppage in 1961.

Wages were raised by 4.25 percent at the beginning of the first and second years, and by 4.7 percent at the beginning of the third year. The 4.7-percent increase is subject to renegotiation if the Consumer Price Index rises 5.5 percent or more between March 1987 and March 1988.

The company responded to the workers' concern over job security by promising to make every effort to avoid layoffs during the contract period, which ends in May 1989.

Consolidated Edison Co. of New York City and the Utility Workers Union agreed on a 3-year contract for 14,500 workers. It provides for 4-percent wage increases in June of 1986, 1987, and 1988. The employees also received an immediate $100 lump-sum payment for ratifying the accord before June 22.

The contract provides for a $250 annual allowance for employees who use their cars on the job; a choice of three health insurance plans (previously, only one plan was available) and two dental plans (previously, one plan); and improved early retirement benefits.

OSHA issues new asbestos standards

The Department of Labor's Occupational Safety and Health Administration has adopted stricter standards for worker exposure to asbestos. The new standards differ for the construction industry and the general industry. Secretary of Labor William Brock said the standards will "substantially increase protections for more than 1.3 million workers and reduce their risk of cancer and other serious disease."

The new limit for exposure to asbestos is 0.2 fiber per cubic centimeter of airspace, averaged over an 8-hour day. This limit, although one-tenth the level in effect since 1976, drew criticism from organized labor. The AFL-CIO described the change as "significant progress" but said the new limit came only "after years of delay" and that workers will still be endangered.

The Associated General Contractors, comprising 8,500 construction firms, contended that the limit is too stringent. The Asbestos Information Association, an employer group, and industry in general, had backed the 0.5 fiber per cubic centimeter limit OSHA had proposed in 1984.

OSHA said the 0.2 limit will benefit 1.3 million employees above the 0.1 fiber per cubic centimeter "action level" at which employers must begin some monitoring, training, and corrective measures. The agency estimated that the 0.2 requirement will reduce the number of asbestos-caused cancer deaths from 64 of 1,000 exposed workers to 6.7, and that it expects the number of asbestosis cases to drop from 50 of 1,000 exposed workers to 5.

The standards require all employers to:

- Alert workers to the dangers of asbestos and train them in safe work practices.
- Distribute respirators to workers in situations where air quality can not be reduced to the acceptable level through engineering controls and work practices.
- Distribute respirators to maintenance employees and in emergencies.
- Post warning signs and labels.
- Keep employee medical and exposure records for at least 30 years.
- Separate change rooms, showers, and lunch rooms when the fiber content of air exceeds the limit.
- Provide medical monitoring of employees when the action level is attained for workers under the general industry standard, and when it is maintained for at least 30 days or negative pressure respirators are used for those under the construction standard.

In addition, the new standards require construction employers to:

- Provide negative pressure enclosures to prevent the escape of asbestos fibers to other areas.
- Provide employee decontamination areas.
- Select a "competent person" to identify existing hazards and take corrective action.

OSHA will continue to require employers to use engineering controls and work practices for protecting workers from excessive exposure to asbestos, which is derived from a mineral and used in textiles, insulation, and other building materials. This approach is favored by unions, which objected to the agency's original proposal, which called for use of "any feasible combination" of engineering controls, work practices, and protective equipment. □

Book Reviews

A monument to the labor movement

The Samuel Gompers Papers: Vol. I, The Making of a Union Leader, 1850–86. Edited by Stuart B. Kaufman. Champaign, IL, University of Illinois Press, 1986. 529 pp. $39.95.

This is the first of a projected 12-volume series of documentary papers of and about Sam Gompers. This first volume takes the reader from the poorest section of London (his parents' marriage certificate, 1849, and SG's birth certificate, 1850), the passenger list of the ship *London* in which the family arrived in New York in 1863, to Gompers' election as the first president of the new American Federation of Labor, 1886.

All labor history buffs have a treat in store for them as they follow through Gompers' eyes the workingman's efforts at organization in the turbulent post-Civil War industrial era. Readers will enjoy learning more about the institutions, politics, and mores of that period. Here we find the ethnic splits in Gompers' union, the Cigarmakers, the ideological split between the Knights of Labor and the trade unions, and the continuing thrusts and parries between those who put first the building of socialism and those who put first the building of trade unions. In the middle of all this strides Gompers, young and vigorous, very sure of his facts and his views, and working ceaselessly.

Two highlights are worthy of special mention. The first is Gompers' testimony, at age 33, before the U.S. Senate Education and Labor Committee, documenting wages and working conditions, explaining the reasoning behind the movement for an 8-hour day, giving details of individual strikes along with his personal philosophy of trade unionism. Sixty-six fascinating pages of testimony.

The second concerns Gompers' efforts in 1881, as an official of the Cigarmakers, to outlaw by legislation the practice of manufacturing cigars in New York City tenements. Gompers personally conducted a special investigation into the practice of employers who used tenement families to roll cigars in their two-room tenement flats, which were filled from morning to night with tobacco leaf and its attendant tobacco dust. His extensive report included case histories of individual contractors and individual tenement houses, as well as medical evidence of the deleterious effects of tobacco, expecially on pregnant women and their chances for healthy births. This, 83 years before the Su geon General's Report on cigarette smoking.

This is the work of many hands. Stuart Kaufman, alor with four associate and two contributing editors, faced herculean task inasmuch as Gompers' papers had been sca tered to the four winds (and some destroyed). Since its sta in 1973, the project has gathered speed and the next tw volumes are nearing publication. The book's format is help ful to the reader. Documents are grouped together, roughl chronologically, with introductory notes clarifying event and identifying individuals.

It's true that basic labor history can be more easily ob tained elsewhere, but the letters, newspaper articles, organi zation reports, committee minutes, and convention proceed ings endow history with the stuff of reality. You are there Don't miss it.

Arlington, VA

Book notes

Employment Termination: Rights and Remedies. By William J. Holloway and Michael J. Leech. Washington, The Bureau of National Affairs, Inc., 1985. 567 pp. $70. Available from BNA Books, Distribution and Customer Service Center, 9435 Key West Avenue, Rockville, MD 20850–3397.

"This book covers a most significant area of the law which, for all practical purposes, didn't exist until only a few years ago. The black-letter rule used to be . . . that the 'at will' employee could be fired 'for any reason, for an improper reason, or for no reason at all.' The rule had been handed down and repeated virtually without question or exception from medieval times—seemingly since the beginning of time."

Employment Termination covers principal contract issues concerning the formation, performance, and termination of employment contracts; common law, statutory, and constitutional claims that often follow in the wake of an alleged wrongful discharge; preclusions, procedural issues, and preemption doctrines which may limit employee causes of action related to discharge; the rights of private voluntary associations and their decisions to admit or exclude members; legal remedies, measures of damages, and equitable remedies of reinstatement and injunction against discharge. Also included is a comprehensive State-by-State listing of employee protection statutes.

A Decade of New Opportunity: Affirmative Action in the 1970's. By Herbert Hammerman. Washington, The Potomac Institute, Inc., 1984. 100 pp. $6, paper.

In contrast to an earlier (1973) Potomac Institute study—which concluded that "more than a decade of affirmative action policy has yielded woefully inadequate results"—this study reports that women and minorities have made substantial progress in the work force in recent years, largely as a result of affirmative action programs. Hammerman says that "the gains have been uneven, and in most areas, parity is still remote. But the trend is unmistakably in the direction of equal opportunity, particularly in the higher positions that were for so long closed to the traditional victims of discrimination."

NOTES ON CURRENT LABOR STATISTICS

This section of the *Review* presents the principal statistical series collected and calculated by the Bureau of Labor Statistics: series on labor force, employment, unemployment, collective bargaining settlements, consumer, producer, and international prices, productivity, international comparisons, and injury and illness statistics. In the notes that follow, the data in each group of tables is briefly described, key definitions are given, notes on the data are set forth, and sources of additional information are cited.

General notes

The following notes apply to several tables in this section:

Seasonal adjustment. Certain monthly and quarterly data are adjusted to eliminate the effect on the data of such factors as climatic conditions, industry production schedules, opening and closing of schools, holiday buying periods, and vacation practices, which might prevent short-term evaluation of the statistical series. Tables containing data that have been adjusted are identified as "seasonally adjusted." (All other data are not seasonally adjusted.) Seasonal effects are estimated on the basis of past experience. When new seasonal factors are computed each year, revisions may affect seasonally adjusted data for several preceding years. (Seasonally adjusted data appear in tables 1–3, 4–10, 13, 14, and 18.) Beginning in January 1980, the BLS introduced two major modifications in the seasonal adjustment methodology for labor force data. First, the data are being seasonally adjusted with a new procedure called X–11 ARIMA, which was developed at Statistics Canada as an extension of the standard X–11 method previously used by BLS. A detailed description of the procedure appears in *The X–11 ARIMA Seasonal Adjustment Method* by Estla Bee Dagum (Statistics Canada, Catalogue No. 12–564E, January 1983). The second change is that seasonal factors are now being calculated for use during the first 6 months of the year, rather than for the entire year, and then are calculated at mid-year for the July-December period. However, revisions of historical data continue to be made only at the end of each calendar year.

Seasonally adjusted labor force data in tables 1 and 4–10 were revised in the February 1986 issue of the *Review*, to reflect experience through 1985.

Annual revisions of the seasonally adjusted payroll data shown in tables 13, 14, and 18 were made in July 1985 using the X–11 ARIMA seasonal adjustment methodology. New seasonal factors for productivity data in table 42 are usually introduced in the September issue. Seasonally adjusted indexes and percent changes from month to month and from quarter to quarter are published for numerous Consumer and Producer Price Index series. However, seasonally adjusted indexes are not published for the U.S. average All Items CPI. Only seasonally adjusted percent changes are available for this series.

Adjustments for price changes. Some data—such as the Hourly Earnings Index in table 17—are adjusted to eliminate the effect of changes in price. These adjustments are made by dividing current dollar values by the Consumer Price Index or the appropriate component of the index, then multiplying by 100. For example, given a current hourly wage rate of $3 and a current price index number of 150, where 1967 = 100, the hourly rate expressed in 1967 dollars is $2 ($3/150 × 100 = $2). The $2 (or any other resulting values) are described as "real," "constant," or "1967" dollars.

Additional information

Data that supplement the tables in this section are published by the Bureau in a variety of sources. Press releases provide the latest statistical information published by the Bureau; the major recurring releases are published according to the schedule preceding these general notes. More information about labor force, employment, and unemployment data and the household and establishment surveys underlying the data are available in *Employment and Earnings*, a monthly publication of the Bureau. More data from the household survey is published in the two-volume data book—*Labor Force Statistics Derived From the Current Population Survey*, Bulletin 2096. More data from the establishment survey appears in two data books—*Employment, Hours, and Earnings, United States*, and *Employment, Hours, and Earnings, States and Areas*, and the annual supplements to these data books. More detailed information on employee compensation and collective bargaining settlements is published in the monthly periodical, *Current Wage Developments*. More detailed data on consumer and producer prices are published in the monthly periodicals, *The CPI Detailed Report*, and *Producer Prices and Price Indexes*. Detailed data on all of the series in this section are provided in the *Handbook of Labor Statistics*, which is published biennally by the Bureau. BLS bulletins are issued covering productivity, injury and illness, and other data in this section. Finally, the *Monthly Labor Review* carries analytical articles on annual and longer term developments in labor force, employment and unemployment; employee compensation and collective bargaining; prices; productivity; international comparisons; and injury and illness data.

Symbols

p = preliminary. To increase the timeliness of some series, preliminary figures are issued based on representative but incomplete returns.
r = revised. Generally, this revision reflects the availability of later data but may also reflect other adjustments.
n.e.c. = not elsewhere classified.
n.e.s. = not elsewhere specified.

COMPARATIVE INDICATORS

(Tables 1–3)

Comparative indicators tables provide an overview and comparison of major BLS statistical series. Consequently, although many of the included series are available monthly, all measures in these comparative tables are presented quarterly and annually.

Labor market indicators include employment measures from two major surveys and information on rates of change in compensation provided by the Employment Cost Index (ECI) program. The labor force participation rate, the employment-to-population ratio, and unemployment rates for major demographic groups based on the Current Population ("household") Survey are presented, while measures of employment and average weekly hours by major industry sector are given using nonagricultural payroll data. The Employment Cost Index (compensation), by major sector and by bargaining status, is chosen from a variety of BLS compensation and wage measures because it provides a comprehensive measure of employer costs for hiring labor, not just outlays for wages, and it is not affected by employment shifts among occupations and industries.

Data on **changes in compensation, prices, and productivity** are presented in table 2. Measures of rates of change of compensation and wages from the Employment Cost Index program are provided for all civilian

nonfarm workers (excluding Federal and household workers) and for all private nonfarm workers. Measures of changes in: consumer prices for all urban consumers; producer prices by stage of processing; and the overall export and import price indexes are given. Measures of productivity (output per hour of all persons) are provided for major sectors.

Alternative measures of wage and compensation rates of change, which reflect the overall trend in labor costs, are summarized in table 3. Differences in concepts and scope, related to the specific purposes of the series, contribute to the variation in changes among the individual measures.

Notes on the data

Definitions of each series and notes on the data are contained in later sections of these notes describing each set of data. For detailed descriptions of each data series, see BLS *Handbook of Methods*, Volumes I and II, Bulletins 2134–1 and 2134–2 (Bureau of Labor Statistics, 1982 and 1984, respectively), as well as the additional bulletins, articles, and other publications noted in the separate sections of the *Review*'s "Current Labor Statistics Notes." Historical data for many series are provided in the *Handbook of Labor Statistics, Bulletin 2217* (Bureau of Labor Statistics, 1985). Users may also wish to consult *Major Programs, Bureau of Labor Statistics*, Report 718 (Bureau of Labor Statistics, 1985).

EMPLOYMENT DATA

(Tables 1; 4–21)

Household survey data

Description of the series

EMPLOYMENT DATA in this section are obtained from the Current Population Survey, a program of personal interviews conducted monthly by the Bureau of the Census for the Bureau of Labor Statistics. The sample consists of about 59,500 households selected to represent the U.S. population 16 years of age and older. Households are interviewed on a rotating basis, so that three-fourths of the sample is the same for any 2 consecutive months.

Definitions

Employed persons include (1) all civilians who worked for pay any time during the week which includes the 12th day of the month or who worked unpaid for 15 hours or more in a family-operated enterprise and (2) those who were temporarily absent from their regular jobs because of illness, vacation, industrial dispute, or similar reasons. Members of the Armed Forces stationed in the United States are also included in the employed total. A person working at more than one job is counted only in the job at which he or she worked the greatest number of hours.

Unemployed persons are those who did not work during the survey week, but were available for work except for temporary illness and had looked for jobs within the preceding 4 weeks. Persons who did not look for work because they were on layoff or waiting to start new jobs within the next 30 days are also counted among the unemployed. The **overall unemployment rate** represents the number unemployed as a percent of the labor force, including the resident Armed Forces. The **civilian unemployment rate** represents the number unemployed as a percent of the civilian labor force.

The **labor force** consists of all employed or unemployed civilians plus members of the Armed Forces stationed in the United States. Persons **not in the labor force** are those not classified as employed or unemployed; this group includes persons who are retired, those engaged in their own housework, those not working while attending school, those unable to work because of long-term illness, those discouraged from seeking work because of personal or job market factors, and those who are voluntarily idle. The **noninstitutional population** comprises all persons 16 years of age and older who are not inmates of penal or mental institutions, sanitariums, or homes for the aged, infirm, or needy, and members of the Armed Forces stationed in the United States. The **labor force participation rate** is the proportion of the noninstitutional populaton that is in the labor force. The **employment-population ratio** is total employment (including the resident Armed Forces) as a percent of the noninstitutional population.

Notes on the data

From time to time, and especially after a decennial census, adjustments are made in the Current Population Survey figures to correct for estimating errors during the preceding years. These adjustments affect the comparability of historical data. A description of these adjustments and their effect on the various data series appear in the Explanatory Notes of *Employment and Earnings*.

Data in tables 4–10 are seasonally adjusted, based on the seasonal experience through December 1984.

Additional sources of information

For detailed explanations of the data, see BLS *Handbook of Methods*, Bulletin 2134–1 (Bureau of Labor Statistics, 1982), chapter 1, and for additional data, *Handbook of Labor Statistics*, Bulletin 2217 (Bureau of Labor Statistics, 1985). A detailed description of the Current Population Survey as well as additional data are available in the monthly Bureau of Labor Statistics periodical, *Employment and Earnings*. Historical data from 1948 to 1982 are available in *Labor Force Statistics Derived from the Current Population Survey: A Databook*, Vols. I and II, Bulletin 2096 (Bureau of Labor Statistics, 1982).

A comprehensive discussion of the differences between household and establishment data on employment appears in Gloria P. Green, "Comparing employment estimates from household and payroll surveys," *Monthly Labor Review*, December 1969, pp. 9–20.

Establishment survey data

Description of the series

EMPLOYMENT, HOURS, AND EARNINGS DATA in this section are compiled from payroll records reported monthly on a voluntary basis to the Bureau of Labor Statistics and its cooperating State agencies by more than 200,000 establishments representing all industries except agriculture. In most industries, the sampling probabilities are based on the size of the establishment; most large establishments are therefore in the sample. (An establishment is not necessarily a firm; it may be a branch plant, for example, or warehouse.) Self-employed persons and others not on a regular civilian payroll are outside the scope of the survey because they are excluded from establishment records. This largely accounts for the difference in employment figures between the household and establishment surveys.

Definitions

An **establishment** is an economic unit which produces goods or services (such as a factory or store) at a single location and is engaged in one type of economic activity.

Employed persons are all persons who received pay (including holiday

and sick pay) for any part of the payroll period including the 12th of the month. Persons holding more than one job (about 5 percent of all persons in the labor force) are counted in each establishment which reports them.

Production workers in manufacturing include blue-collar worker supervisors and all nonsupervisory workers closely associated with production operations. Those workers mentioned in tables 12–16 include production workers in manufacturing and mining; construction workers in construction; and nonsupervisory workers in the following industries: transportation and public utilities; wholesale and retail trade; finance, insurance, and real estate; and services. These groups account for about four-fifths of the total employment on private nonagricutural payrolls.

Earnings are the payments production or nonsupervisory workers receive during the survey period, including premium pay for overtime or late-shift work but excluding irregular bonuses and other special payments. **Real earnings** are earnings adjusted to reflect the effects of changes in consumer prices. The deflator for this series is derived from the Consumer Price Index for Urban Wage Earners and Clerical Workers (CPI-W). The **Hourly Earnings Index** is calculated from average hourly earnings data adjusted to exclude the effects of two types of changes that are unrelated to underlying wage-rate developments: fluctuations in overtime premiums in manufacturing (the only sector for which overtime data are available) and the effects of changes and seasonal factors in the proportion of workers in high-wage and low-wage industries.

Hours represent the average weekly hours of production or nonsupervisory workers for which pay was received and are different from standard or scheduled hours. **Overtime hours** represent the portion of gross average weekly hours which were in excess of regular hours and for which overtime premiums were paid.

The Diffusion Index, introduced in the May 1983 *Review*, represents the percent of 185 nonagricultural industries in which employment was rising over the indicated period. One-half of the industries with unchanged employment are counted as rising. In line with Bureau practice, data for the 1-, 3-, and 6-month spans are seasonally adjusted, while those for the 12-month span are unadjusted. The diffusion index is useful for measuring the dispersion of economic gains or losses and is also an economic indicator.

Notes on the data

Establishment data collected by the Bureau of Labor Statistics are periodically adjusted to comprehensive counts of employment (called "benchmarks"). The latest complete adjustment was made with the release of May 1985 data, published in the July 1985 issue of the *Review*. Consequently, data published in the *Review* prior to that issue are not necessarily comparable to current data. Unadjusted data have been revised back to April 1983; seasonally adjusted data have been revised back to January 1980. These revisions were published in the *Supplement to Employment and Earnings* (Bureau of Labor Statistics, 1985). Unadjusted data from April 1984 forward, and seasonally adjusted data from January 1981 forward are subject to revision in future benchmarks.

Additional sources of information

Detailed data from the establishment survey are published monthly in the BLS periodical, *Employment and Earnings*. Earlier comparable unadjusted and seasonally adjusted data are published in *Employment, Hours, and Earnings, United States, 1909–84*, Bulletin 1312–12 (Bureau of Labor Statistics, 1985) and its annual supplement. For a detailed discussion of the methodology of the survey, see *BLS Handbook of Methods*, Bulletin 2134–1 (Bureau of Labor Statistics, 1982), chapter 2. For additional data, see *Handbook of Labor Statistics*, Bulletin 2217 (Bureau of Labor Statistics, 1985).

A comprehensive discussion of the differences between household and establishment data on employment appears in Gloria P. Green, "Comparing employment estimates from household and payroll surveys," *Monthly Labor Review*, December 1969, pp. 9–20.

Unemployment data by State

Description of the series

Data presented in this section are obtained from two major sources—the Current Population Survey (CPS) and the Local Area Unemployment Statistics (LAUS) program, which is conducted in cooperation with State employment security agencies.

Monthly estimates of the labor force, employment, and unemployment for States and sub-State areas are a key indicator of local economic conditions and form the basis for determining the eligibility of an area for benefits under Federal economic assistance programs such as the Job Training Partnership Act and the Public Works and Economic Development Act. Insofar as possible, the concepts and definitions underlying these data are those used in the national estimates obtained from the CPS.

Notes on the data

Data refer to State of residence. Monthly data for 11 States—California, Florida, Illinois, Massachusetts, Michigan, New York, New Jersey, North Carolina, Ohio, Pennsylvania, and Texas—are obtained directly from the CPS, because the size of the sample is large enough to meet BLS standards of reliability. Data for the remaining 39 States and the District of Columbia are derived using standardized procedures established by BLS. Once a year, estimates for the 11 States are revised to new population controls. For the remaining States and the District of Columbia, data are benchmarked to annual average CPS levels.

Additional sources of information

Information on the concepts, definitions, and technical procedures used to develop labor force data for States and sub-State areas as well as additional data on sub-States are provided in the monthly Bureau of Labor Statistics periodical, *Employment and Earnings*, and the annual report, *Geographic Profile of Employment and Unemployment* (Bureau of Labor Statistics). See also *BLS Handbook of Methods*, Bulletin 2134–1 (Bureau of Labor Statistics, 1982), chapter 4.

COMPENSATION AND WAGE DATA

(Tables 1–3; 22–29)

COMPENSATION AND WAGE DATA are gathered by the Bureau from business establishments, State and local governments, labor unions, collective bargaining agreements on file with the Bureau, and secondary sources.

Employment Cost Index

Description of the series

The **Employment Cost Index** (ECI) is a quarterly measure of the rate of change in compensation per hour worked and includes wages, salaries, and employer costs of employee benefits. It uses a fixed market basket of labor—similar in concept to the Consumer Price Index's fixed market basket of goods and services—to measure change over time in employer costs of employing labor. The index is not seasonally adjusted.

Statistical series on total compensation costs and on wages and salaries are available for private nonfarm workers excluding proprietors, the self-employed, and household workers. Both series are also available for State and local government workers and for the civilian nonfarm economy, which consists of private industry and State and local government workers combined. Federal workers are excluded.

The Employment Cost Index probability sample consists of about 2,200 private nonfarm establishments providing about 12,000 occupational observations and 700 State and local government establishments providing

3,500 occupational observations selected to represent total employment in each sector. On average, each reporting unit provides wage and compensation information on five well-specified occupations. Data are collected each quarter for the pay period including the 12th day of March, June, September, and December.

Fixed employment weights from the 1970 Census of Population are used each quarter to calculate the indexes for civilian, private, and State and local governments. These fixed weights, also used to derive all of the industry and occupation series indexes, ensure that changes in these indexes reflect only changes in compensation, not employment shifts among industries or occupations with different levels of wages and compensation. For the bargaining status, region, and metropolitan/nonmetropolitan area series, however, employment data by industry and occupation are not available from the census. Instead, the 1970 employment weights are reallocated within these series each quarter based on the current sample. Therefore, these indexes are not strictly comparable to those for the aggregate, industry, and occupation series.

Definitions

Total compensation costs include wages, salaries, and the employer costs for employee benefits.

Wages and salaries consist of earnings before payroll deductions, including production bonuses, incentive earnings, commissions, and cost-of-living adjustments.

Benefits include the cost to employers for paid leave, supplemental pay (including nonproduction bonuses), insurance, retirement and savings plans, and legally required benefits (such as social security, workers' compensation, and unemployment insurance).

Excluded from wages and salaries and employee benefits are such items as payment-in-kind, free room and board, and tips.

Notes on the data

The Employment Cost Index data series began in the fourth quarter of 1975, with the quarterly percent change in wages and salaries in the private nonfarm sector. Data on employer costs for employee benefits were included in 1980 to produce, when combined with the wages and salaries series, a measure of the percent change in employer costs for employee total compensation. State and local government units were added to the ECI coverage in 1981, providing a measure of total compensation change in the *civilian* nonfarm economy (excluding Federal employees). Historical indexes (June 1981=100) of the quarterly rates of change are presented in the May issue of the BLS monthly periodical, *Current Wage Developments*.

Additional sources of information

For a more detailed discussion of the Employment Cost Index, see Chapter 11, "The Employment Cost Index," in the *Handbook of Methods*, Bulletin 2134–1 (Bureau of Labor Statistics, 1982), and the following *Monthly Labor Review* articles: "Employment Cost Index: a measure of change in the 'price of labor'," July 1975; "How benefits will be incorporated into the Employment Cost Index," January 1978; "Estimation procedures for the Employment Cost Index," May 1982; and "Introducing new weights for the Employment Cost Index," June 1985.

Data on the ECI are also available in BLS quarterly press releases issued in the month following the reference months of March, June, September, and December; and from the *Handbook of Labor Statistics*, Bulletin 2217 (Bureau of Labor Statistics, 1985).

Collective bargaining settlements

Description of the series

Collective bargaining settlements data provide statistical measures of negotiated adjustments (increases, decreases, and freezes) in compensation (wages and benefits costs) and wages alone, quarterly for private industry and semiannually for State and local government. Compensation measures cover all collective bargaining situations involving 5,000 workers or more and wage measures cover all situations involving 1,000 workers or more. These data, covering private nonagricultural industries and State and local governments, are calculated using information obtained from bargaining agreements on file with the Bureau, parties to the agreements, and secondary sources, such as newspaper accounts. The data are not seasonally adjusted.

Settlement data are measured in terms of future specified adjustments: those that will occur within 12 months after contract ratification—first year—and all adjustments that will occur over the life of the contract expressed as an average annual rate. Adjustments are worker weighted. Both first-year and over-the-life measures exclude wage changes that may occur under cost-of-living clauses that are triggered by future movements in the Consumer Price Index.

Effective wage adjustments measure all adjustments occurring in the reference period, regardless of the settlement date. Included are changes from settlements reached during the period, changes deferred from contracts negotiated in earlier periods, and changes under cost-of-living adjustment clauses. Each wage change is worker weighted. The changes are prorated over all workers under agreements during the reference period yielding the average adjustment.

Definitions

Wage rate changes are calculated by dividing newly negotiated wages by the average hourly earnings, excluding overtime, at the time the agreement is reached. Compensation changes are calculated by dividing the change in the value of the newly negotiated wage and benefit package by existing average hourly compensation, which includes the cost of previously negotiated benefits, legally required social insurance programs, and average hourly earnings.

Compensation changes are calculated by placing a value on the benefit portion of the settlements at the time they are reached. The cost estimates are based on the assumption that conditions existing at the time of settlement (for example, methods of financing pensions or composition of labor force) will remain constant. The data, therefore, are measures of negotiated changes and not of total changes in employer cost.

Contract duration runs from the effective date of the agreement to the expiration date or first wage reopening date, if applicable. Average annual percent changes over the contract term take account of the compounding of successive changes.

Notes on the data

Care should be exercised in comparing the size and nature of the settlements in State and local government with those in the private sector because of differences in bargaining practices and settlement characteristics. A principal difference is the incidence of cost-of-living adjustment (COLA) clauses which cover only about 2 percent of workers under a few local government settlements, but cover 50 percent of workers under private sector settlements. Agreements without COLA's tend to provide larger specified wage increases than those with COLA's. Another difference is that State and local government bargaining frequently excludes pension benefits which are often prescribed by law. In the private sector, in contrast, pensions are typically a bargaining issue.

Additional sources of information

For a more detailed discussion on the series, see of the BLS *Handbook of Methods*, Bulletin 2134–1 (Bureau of Labor Statistics, 1982), chapter 10. Comprehensive data are published in press releases issued quarterly (in January, April, July, and October) for private industry, and semi-

annually (in February and August) for State and local government. Historical data and additional detailed tabulations for the prior calendar year appear in the April issue of the BLS monthly periodical, *Current Wage Developments*.

Work stoppages

Description of the series

Data on **work stoppages** measure the number and duration of major strikes or lockouts (involving 1,000 workers or more) occurring during the month (or year), the number of workers involved, and the amount of time lost because of stoppage.

Data are largely from newspaper accounts and cover only establishments directly involved in a stoppage. They do not measure the indirect or secondary effect of stoppages on other establishments whose employees are idle owing to material shortages or lack of service.

Definitions

Number of stoppages: The number of strikes and lockouts involving 1,000 workers or more and lasting a full shift or longer.

Workers involved: The number of workers directly involved in the stoppage.

Number of days idle: The aggregate number of work days lost by workers involved in the stoppages.

Days of idleness as a percent of estimated working time: Aggregate work days lost as a percent of the aggregate number of standard work days in the period multiplied by total employment in the period.

Notes on the data

This series is not comparable with the one terminated in 1981 that covered strikes involving six workers or more.

Additional sources of information

Data for each calendar year are reported in a BLS press release issued in the first quarter of the following year. Monthly data appear in the BLS monthly periodical, *Current Wage Developments*. Historical data appear in the *BLS Handbook of Labor Statistics*.

Other compensation data

Other BLS data on pay and benefits, not included in the Current Labor Statistics section of the *Monthly Labor Review*, appear in and consist of the following:

Industry Wage Surveys provide data for specific occupations selected to represent an industry's wage structure and the types of activities performed by its workers. The Bureau collects information on weekly work schedules, shift operations and pay differentials, paid holiday and vacation practices, and information on incidence of health, insurance, and retirement plans. Reports are issued throughout the year as the surveys are completed. Summaries of the data and special analyses also appear in the *Monthly Labor Review*.

Area Wage Surveys annually provide data for selected office, clerical, professional, technical, maintenance, toolroom, powerplant, material movement, and custodial occupations common to a wide variety of industries in the areas (labor markets) surveyed. Reports are issued throughout the year as the surveys are completed. Summaries of the data and special analyses also appear in the *Review*.

The National Survey of Professional, Administrative, Technical, and Clerical Pay provides detailed information annually on salary levels and distributions for the types of jobs mentioned in the survey's title in private employment. Although the definitions of the jobs surveyed reflect the duties and responsibilities in private industry, they are designed to match specific pay grades of Federal white-collar employees under the General Schedule pay system. Accordingly, this survey provides the legally required information for comparing the pay of salaried employees in the Federal civil service with pay in private industry. (See Federal Pay Comparability Act of 1970, 5 U.S.C. 5305.) Data are published in a BLS news release issued in the summer and in a bulletin each fall; summaries and analytical articles also appear in the *Review*.

Employee Benefits Survey provides nationwide information on the incidence and characteristics of employee benefit plans in medium and large establishments in the United States, excluding Alaska and Hawaii. Data are published in an annual BLS news release and bulletin, as well as in special articles appearing in the *Review*.

PRICE DATA
(Tables 2; 30–41)

PRICE DATA are gathered by the Bureau of Labor Statistics from retail and primary markets in the United States. Price indexes are given in relation to a base period (1967 = 100, unless otherwise noted).

Consumer Price Indexes

Description of the series

The **Consumer Price Index** (CPI) is a measure of the average change in the prices paid by urban consumers for a fixed market basket of goods and services. The CPI is calculated monthly for two population groups, one consisting only of urban households whose primary source of income is derived from the employment of wage earners and clerical workers, and the other consisting of all urban households. The wage earner index (CPI–W) is a continuation of the historic index that was introduced well over a half-century ago for use in wage negotiations. As new uses were developed for the CPI in recent years, the need for a broader and more representative index became apparent. The all urban consumer index (CPI–U) introduced in 1978 is representative of the 1972–73 buying habits of about 80 percent of the noninstitutional population of the United States at that time, compared with 40 percent represented in the CPI–W. In addition to wage earners and clerical workers, the CPI–U covers professional, managerial, and technical workers, the self-employed, short-term workers, the unemployed, retirees, and others not in the labor force.

The CPI is based on prices of food, clothing, shelter, fuel, drugs, transportation fares, doctors' and dentists' fees, and other goods and services that people buy for day-to-day living. The quantity and quality of these items are kept essentially unchanged between major revisions so that only price changes will be measured. All taxes directly associated with the purchase and use of items are included in the index.

Data collected from more than 24,000 retail establishments and 24,000 tenants in 85 urban areas across the country are used to develop the "U.S. city average." Separate estimates for 28 major urban centers are presented in table 31. The areas listed are as indicated in footnote 1 to the table. The area indexes measure only the average change in prices for each area since the base period, and do not indicate differences in the level of prices among cities.

Notes on the data

In January 1983, the Bureau changed the way in which homeownership costs are measured for the CPI–U. A rental equivalence method replaced the

asset-price approach to homeownership costs for that series. In January 1985, the same change was made in the CPI-W. The central purpose of the change was to separate shelter costs from the investment component of homeownership so that the index would reflect only the cost of shelter services provided by owner-occupied homes.

Additional sources of information

For a discussion of the general method for computing the CPI, see *BLS Handbook of Methods, Volume II, The Consumer Price Index*, Bulletin 2134–2 (Bureau of Labor Statistics, 1984). The recent change in the measurement of homeownership costs is discussed in Robert Gillingham and Walter Lane, "Changing the treatment of shelter costs for homeowners in the CPI," *Monthly Labor Review*, June 1982, pp. 9–14.

Additional detailed CPI data and regular analyses of consumer price changes are provided in the *CPI Detailed Report*, a monthly publication of the Bureau. Historical data for the overall CPI and for selected groupings may be found in the *Handbook of Labor Statistics*, Bulletin 2217 (Bureau of Labor Statistics, 1985).

Producer price indexes

Description of the series

Producer Price Indexes (PPI) measure average changes in prices received in primary markets of the United States by producers of commodities in all stages of processing. The sample used for calculating these indexes currently contains about 3,200 commodities and about 60,000 quotations per month selected to represent the movement of prices of all commodities produced in the manufacturing, agriculture, forestry, fishing, mining, gas and electricity, and public utilities sectors. The stage of processing structure of Producer Price Indexes organizes products by class of buyer and degree of fabrication (that is, finished goods, intermediate goods, and crude materials). The traditional commodity structure of PPI organizes products by similarity of end-use or material composition.

To the extent possible, prices used in calculating Producer Price Indexes apply to the first significant commercial transaction in the United States from the production or central marketing point. Price data are generally collected monthly, primarily by mail questionnaire. Most prices are obtained directly from producing companies on a voluntary and confidential basis. Prices generally are reported for the Tuesday of the week containing the 13th day of the month.

Since January 1976, price changes for the various commodities have been averaged together with implicit quantity weights representing their importance in the total net selling value of all commodities as of 1972. The detailed data are aggregated to obtain indexes for stage-of-processing groupings, commodity groupings, durability-of-product groupings, and a number of special composite groups. All Producer Price Index data are subject to revision 4 months after original publication.

Notes on the data

Beginning with the January 1986 issue, the *Review* is no longer presenting tables of Producer Price Indexes for commodity groupings, special composite groups, or SIC industries. However, these data will continue to be presented in the Bureau's monthly publication *Producer Price Indexes*.

The Bureau has completed the first major stage of its comprehensive overhaul of the theory, methods, and procedures used to construct the Producer Price Indexes. Changes include the replacement of judgment sampling with probability sampling techniques; expansion to systematic coverage of the net output of virtually all industries in the mining and manufacturing sectors; a shift from a commodity to an industry orientation the exclusion of imports from, and the inclusion of exports in, the survey universe; and the respecification of commodities priced to conform to Bureau of the Census definitions. These and other changes have been phased in gradually since 1978. The result is a system of indexes that is easier to use in conjunction with data on wages, productivity, and employment and other series that are organized in terms of the Standard Industrial Classification and the Census product class designations.

Additional sources of information

For a discussion of the methodology for computing Producer Price Indexes, see *BLS Handbook of Methods*, Bulletin 2134–1 (Bureau of Labor Statistics, 1982), chapter 7.

Additional detailed data and analyses of price changes are provided monthly in *Producer Price Indexes*. Selected historical data may be found in the *Handbook of Labor Statistics*, Bulletin 2217 (Bureau of Labor Statistics, 1985).

International price indexes

Description of the series

The BLS **International Price Program** produces quarterly export and import price indexes for nonmilitary goods traded between the United States and the rest of the world. The export price index provides a measure of price change for all products sold by U.S. residents to foreign buyers. ("Residents" is defined as in the national income accounts: it includes corporations, businesses, and individuals but does not require the organizations to be U.S. owned nor the individuals to have U.S. citizenship.) The import price index provides a measure of price change for goods purchased from other countries by U.S. residents. With publication of an all-import index in February 1983 and an all-export index in February 1984, all U.S. merchandise imports and exports now are represented in these indexes. The reference period for the indexes is 1977 = 100, unless otherwise indicated.

The product universe for both the import and export indexes includes raw materials, agricultural products, semifinished manufactures, and finished manufactures, including both capital and consumer goods. Price data for these items are collected quarterly by mail questionnaire. In nearly all cases, the data are collected directly from the exporter or importer, although in a few cases, prices are obtained from other sources.

To the extent possible, the data gathered refer to prices at the U.S. border for exports and at either the foreign border or the U.S. border for imports. For nearly all products, the prices refer to transactions completed during the first 2 weeks of the third month of each calendar quarter—March, June, September, and December. Survey respondents are asked to indicate all discounts, allowances, and rebates applicable to the reported prices, so that the price used in the calculation of the indexes is the actual price for which the product was bought or sold.

In addition to general indexes of prices for U.S. exports and imports, indexes are also published for detailed product categories of exports and imports. These categories are defined by the 4- and 5-digit level of detail of the Standard Industrial Trade Classification System (SITC). The calculation of indexes by SITC category facilitates the comparison of U.S. price trends and sector production with similar data for other countries. Detailed indexes are also computed and published on a Standard Industrial Classification (SIC-based) basis, as well as by end-use class.

Notes on the data

The export and import price indexes are weighted indexes of the Laspeyeres type. Price relatives are assigned equal importance within each weight category and are then aggregated to the SITC level. The values assigned to each weight category are based on trade value figures compiled

by the Bureau of the Census. The trade weights currently used to compute both indexes relate to 1980.

Because a price index depends on the same items being priced from period to period, it is necessary to recognize when a product's specifications or terms of transaction have been modified. For this reason, the Bureau's quarterly questionnaire requests detailed descriptions of the physical and functional characteristics of the products being priced, as well as information on the number of units bought or sold, discounts, credit terms, packaging, class of buyer or seller, and so forth. When there are changes in either the specifications or terms of transaction of a product, the dollar value of each change is deleted from the total price change to obtain the "pure" change. Once this value is determined, a linking procedure is employed which allows for the continued repricing of the item.

For the export price indexes, the preferred pricing basis is f.a.s. (free alongside ship) U.S. port of exportation. When firms report export prices f.o.b. (free on board), production point information is collected which enables the Bureau to calculate a shipment cost to the port of exportation. An attempt is made to collect two prices for imports. The first is the import price f.o.b. at the foreign port of exportation, which is consistent with the basis for valuation of imports in the national accounts. The second is the import price c.i.f. (cost, insurance, and freight) at the U.S. port of importation, which also includes the other costs associated with bringing the product to the U.S. border. It does not, however, include duty charges.

Additional sources of information

For a discussion of the general method of computing International Price Indexes, see BLS *Handbook of Methods*, Bulletin 2134–1 (Bureau of Labor Statistics, 1982), chapter 8.

Additional detailed data and analyses of international price developments are presented in the Bureau's quarterly publication *U.S. Import and Export Price Indexes* and in occasional *Monthly Labor Review* articles prepared by BLS analysts. Selected historical data may be found in the *Handbook of Labor Statistics*, Bulletin 2217 (Bureau of Labor Statistics, 1985).

PRODUCTIVITY DATA
(Tables 2; 42–47)

U. S. productivity and related data

Description of the series

The productivity measures relate real physical output to real input. As such, they encompass a family of measures which include single factor input measures, such as output per unit of labor input (output per hour) or output per unit of capital input, as well as measures of multifactor productivity (output per unit of labor and capital inputs combined). The Bureau indexes show the change in output relative to changes in the various inputs. The measures cover the business, nonfarm business, manufacturing, and nonfinancial corporate sectors.

Corresponding indexes of hourly compensation, unit labor costs, unit nonlabor payments, and prices are also provided.

Definitions

Output per hour of all persons (labor productivity) is the value of goods and services in constant prices produced per hour of labor input. **Output per unit of capital services** (capital productivity) is the value of goods and services in constant dollars produced per unit of capital services input.

Multifactor productivity is the ratio output per unit of labor and capital inputs combined. Changes in this measure reflect changes in a number of factors which affect the production process such as changes in technology, shifts in the composition of the labor force, changes in capacity utilization, research and development, skill and efforts of the work force, management, and so forth. Changes in the output per hour measures reflect the impact of these factors as well as the substitution of capital for labor.

Compensation per hour is the wages and salaries of employees plus employers' contributions for social insurance and private benefit plans, and the wages, salaries, and supplementary payments for the self-employed (except for nonfinancial corporations in which there are no self-employed)—the sum divided by hours paid for. **Real compensation per hour** is compensation per hour deflated by the change in the Consumer Price Index for All Urban Consumers.

Unit labor costs are the labor compensation costs expended in the production of a unit of output and are derived by dividing compensation by output. **Unit nonlabor payments** include profits, depreciation, interest, and indirect taxes per unit of output. They are computed by subtracting compensation of all persons from current dollar value of output and dividing by output. **Unit nonlabor costs** contain all the components of unit nonlabor payments *except* unit profits.

Unit profits include corporate profits and the value of inventory adjustments per unit of output.

Hours of all persons are the total hours paid of payroll workers, self-employed persons, and unpaid family workers.

Capital services is the flow of services from the capital stock used in production. It is developed from measures of the net stock of physical assets—equipment, structures, land, and inventories—weighted by rental prices for each type of asset.

Labor and capital inputs combined are derived by combining changes in labor and capital inputs with weights which represent each component's share of total output. The indexes for capital services and combined units of labor and capital are based on changing weights which are averages of the shares in the current and preceding year (the Tornquist index-number formula).

Notes on the data

Output measures for the business sector and the nonfarm businesss sector exclude the constant dollar value of owner-occupied housing, rest of world, households and institutions, and general government output from the constant dollar value of gross national product. The measures are derived from data supplied by the Bureau of Economic Analysis, U.S. Department of Commerce, and the Federal Reserve Board. Quarterly manufacturing output indexes are adjusted by the Bureau of Labor Statistics to annual estimates of output (gross product originating) from the Bureau of Economic Analysis. Compensation and hours data are developed from data of the Bureau of Labor Statistics and the Bureau of Economic Analysis.

The productivity and associated cost measures in tables 42–44 describe the relationship between output in real terms and the labor time and capital services involved in its production. They show the changes from period to period in the amount of goods and services produced per unit of input. Although these measures relate output to hours and capital services, they do not measure the contributions of labor, capital, or any other specific factor of production. Rather, they reflect the joint effect of many influences, including changes in technology; capital investment; level of output; utilization of capacity, energy, and materials; the organization of production; managerial skill; and the characteristics and efforts of the work force.

Additional sources of information

Descriptions of methodology underlying the measurement of output per hour and multifactor productivity are found in the BLS *Handbook of Methods*, Bulletin 2134–1 (Bureau of Labor Statistics, 1982), chapter 13. Historical data for selected industries are provided in the Bureau's *Handbook of Labor Statistics*, 1985, Bulletin 2217.

International comparisons

Description of the series

Comparative measures of labor force, employment, and unemployment (tables 45 and 46) are prepared regularly for the United States, Canada, Australia, Japan, France, Germany, Great Britain, Italy, the Netherlands, and Sweden. Unemployment rates, approximating U.S. concepts, are prepared monthly for most of the countries; the other measures, annually.

The Bureau of Labor Statistics also prepares international comparisons of manufacturing labor productivity and labor costs (table 47) that cover the United States and 11 foreign countries—those listed above plus Belgium and Norway. These measures are limited to trend comparisons; that is, intercountry series of changes over time, rather than level comparisons because reliable international comparisons of the levels of manufacturing are unavailable. The U.S. measures are described in the notes on U.S. productivity measurement; the measures for foreign countries are compiled from various national and international data sources.

Definitions

Output measures are constant value output (value added) from the national accounts of each country, except for those for Japan prior to 1970 and for the Netherlands for 1969 forward, which are indexes of industrial production. The national accounting methods for measuring real output differ considerably among the 12 countries, but the use of different procedures does not, in itself, connote lack of comparability—rather, it reflects differences among countries in the availability and reliability of underlying data series.

Hours and compensation measures refer to all employed persons including the self-employed in the United States and Canada, and to all wage and salary employees in the other countries. *Hours* refer to hours *paid* in the United States, hours *worked* in the other countries. *Compensation (labor costs)* includes not only all payments made directly to employees and employer expenditures for social insurance and private benefit plans, but changes in significant employment or payroll taxes that are not compensation to employees but are labor costs to employers (France, Sweden, and the United Kingdom). Self-employed workers are included in the U.S. and Canadian figures by assuming that their hourly compensation is equal to the average for wage and salary employees.

Notes on the data

The data for the foreign countries in tables 45 and 46 have been adjusted, where necessary, for greater comparability with U.S. definitions of employment and unemployment. The adjusted statistics have been adapted to the age at which compulsory schooling ends in each country. Therefore, the adjusted statistics relate to the civilian population age 16 and over in the United States, France, and Sweden, and from 1973 forward, Great Britain; 15 and over in Canada, Australia, Japan, Germany, and the Netherlands; and 14 and over in Italy. Prior to 1973, the data for Great Britain related to persons age 15 and over. The institutional population is included in the denominator of the labor force participation rates and employment-population ratios for Japan and Germany.

For most of the countries in table 47, the measures refer to total manufacturing as defined by the International Standard Industrial Classification. However, the measures for France (beginning 1959), Italy (beginning 1970), and the United Kingdom (beginning 1976) refer to manufacturing and mining less energy-related products. For all countries, manufacturing includes the activities of government enterprises.

In addition, for all countries, preliminary estimates for recent years are generally based on current indicators of manufacturing output, employment and hours, and hourly compensation until national accounts and other statistics used for the long-term measures become available.

Additional sources of information

For further information, see *International Comparisons of Unemployment*, Bulletin 1979 (Bureau of Labor Statistics, 1978), Appendix B and Supplements to Appendix B. Additional detail is also found in the BLS *Handbook of Methods*, Bulletin 2134–1 (Bureau of Labor Statistics, 1982), chapter 16. Additional international comparison statistics are available in the *Handbook of Labor Statistics*, Bulletin 2217 (Bureau of Labor Statistics, 1985). The most recent statistics are presented and analyzed annually in the *Monthly Labor Review*, typically in the December issue (for the previous year) and in February.

OCCUPATIONAL INJURY AND ILLNESS DATA

(Table 48)

Description of the series

The Annual Survey of Occupational Injuries and Illnesses is designed to collect data on injuries and illnesses based on records which employers in the following industries maintain under the Occupational Safety and Health Act of 1970: agriculture, forestry, and fishing; oil and gas extraction; construction; manufacturing; transportation and public utilities; wholesale and retail trade; finance, insurance, and real estate; and services. Excluded from the survey are self-employed individuals, farmers with fewer than 11 employees, employers regulated by other Federal safety and health laws, and Federal, State, and local government agencies.

Because the survey is a Federal–State cooperative program and the data must meet the needs of participating State agencies, an independent sample is selected for each State. The sample is selected to represent all private industries in the States and territories. The sample size for the survey is dependent upon (1) the characteristics for which estimates are needed; (2) the industries for which estimates are desired; (3) the characteristics of the population being sampled; (4) the target reliability of the estimates; and (5) the survey design employed.

While there are many characteristics upon which the sample design could be based, the total recorded case incidence rate is used because it is one of the most important characteristics and the least variable; therefore, it requires the smallest sample size.

The survey is based on stratified random sampling with a Neyman allocation and a ratio estimator. The characteristics used to stratify the establishments are the Standard Industrial Classification (SIC) code and size of employment.

Definitions

Recordable occupational injuries and illnesses are: (1) occupational deaths, regardless of the time between injury and death, or the length of the illness; or (2) nonfatal occupational illnesses; or (3) nonfatal occupational injuries which involve one or more of the following: loss of consciousness, restriction of work or motion, transfer to another job, or medical treatment (other than first aid).

Occupational injury is any injury such as a cut, fracture, sprain, amputation, and so forth, which results from a work accident or from exposure involving a single incident in the work environment.

Occupational illness is an abnormal condition or disorder, other than one resulting from an occupational injury, caused by exposure to environmental factors associated with employment. It includes acute and chronic illnesses or disease which may be caused by inhalation, absorption, ingestion, or direct contact.

Lost workday cases are cases which involve days away from work, or days of restricted work activity, or both.

Lost workday cases involving restricted work activity are those cases which result in restricted work activity only.

Lost workdays away from work are the number of workdays (consecutive or not) on which the employee would have worked but could not because of occupational injury or illness.

Lost workdays—restricted work activity are the number of workdays (consecutive or not) on which, because of injury or illness: (1) the employee was assigned to another job on a temporary basis; or (2) the employee worked at a permanent job less than full time; or (3) the employee worked at a permanently assigned job but could not perform all duties normally connected with it.

The number of days away from work or days of restricted work activity does not include the day of injury or onset of illness or any days on which the employee would not have worked even though able to work.

Incidence rates represent the number of injuries and/or illnesses or lost workdays per 100 full-time workers.

Notes on the data

Estimates are made for industries and employment-size classes and for severity classification: fatalities, lost workday cases, and nonfatal cases without lost workdays. Lost workday cases are separated into those where the employee would have worked but could not and those in which work activity was restricted. Estimates of the number of cases and the number of days lost are made for both categories.

Most of the estimates are in the form of incidence rates, defined as the number of injuries and illnesses, or lost workdays, per 100 full-time employees. For this purpose, 200,000 employee hours represent 100 employee years (2,000 hours per employee). Only a few of the available measures are included in the *Handbook of Labor Statistics*. Full detail is presented in the annual bulletin, *Occupational Injuries and Illnesses in the United States, by Industry*.

Comparable data for individual States are available from the BLS Office of Occupational Safety and Health Statistics.

Mining and railroad data are furnished to BLS by the Mine Safety and Health Administration and the Federal Railroad Administration, respectively. Data from these organizations are included in BLS and State publications. Federal employee experience is compiled and published by the Occupational Safety and Health Administration. Data on State and local government employees are collected by about half of the States and territories; these data are not compiled nationally.

Additional sources of information

The Supplementary Data System provides detailed information describing various factors associated with work-related injuries and illnesses. These data are obtained from information reported by *employers* to State workers' compensation agencies. The Work Injury Report program examines selected types of accidents through an employee survey which focuses on the circumstances surrounding the injury. These data are not included in the *Handbook of Labor Statistics* but are available from the BLS Office of Occupational Safety and Health Statistics.

The definitions of occupational injuries and illnesses and lost workdays are from *Recordkeeping Requirements under the Occupational Safety and Health Act of 1970*. For additional data, see *Occupational Injuries and Illnesses in the United States, by Industry*, annual Bureau of Labor Statistics bulletin; BLS *Handbook of Methods*, Bulletin 2134–1 (Bureau of Labor Statistics, 1982), chapter 17; *Handbook of Labor Statistics*, Bulletin 2217 (Bureau of Labor Statistics, 1985), pp. 411–14; annual reports in the *Monthly Labor Review*; and annual U.S. Department of Labor press releases.

1. Labor market indicators

Selected indicators	1984	1985	1984			1985				1986
			II	III	IV	I	II	III	IV	I
Employment data										
Employment status of the civilian noninstitutionalized population (household survey)[1]

---

[1] Cost (cents-per-hour worked) measured in the Employment Cost Index consists of wages, salaries, and employer cost of employee benefits.

[2] Consist of private industry workers (excluding farm and household workers) and State and local government (excluding Federal Government) workers.

[3] Consists of legislative, judicial, administrative, and regulatory activities.

[4] Includes, for example, library, social, and health services

[1] The indexes are calculated differently from those for the occupation and industry groups. For a detailed description of the index calculation, see the *Monthly Labor Review* Technical Note, "Estimation procedures for the Employment Cost Index," May 1982.

25. Specified compensation and wage adjustments from contract settlements, and effective wage adjustments, private industry collective bargaining situations covering 1,000 workers or more (in percent)

Measure	Annual average		Quarterly average							
	1984	1985	1984			1985				1986
			II	III	IV	I	II	III	IV	I^p
Specified adjustments:										
Total compensation[1] adjustments,[2] settlements covering 5,000 workers or more:										
First year of contract	3.6	2.6	3.5	2.7	3.7	3.6	3.5	2.0	2.0	0.3
Annual rate over life of contract	2.8	2.7	3.2	3.1	2.0	2.7	3.4	3.0	1.4	1.2
Wage adjustments, settlements covering 1,000 workers or more.										
First year of contract	2.4	2.3	2.6	2.1	2.3	3.3	2.5	2.0	2.1	.8
Annual rate over life of contract	2.4	2.7	2.7	2.6	1.5	3.2	2.8	3.1	1.9	1.6
Effective adjustments:										
Total effective wage adjustment[3]	3.7	3.3	.9	1.2	.7	.7	.8	1.2	.5	.6
From settlements reached in period	.8	.7	.1	.2	.3	.1	.2	.2	.1	.0
Deferred from settlements reached in earlier periods	2.0	1.6	.7	.7	.2	.6	.5	.5	.2	.4
From cost-of-living-adjustments clauses	.9	.7	.2	.3	.2	.1	.1	.4	.1	.2

[1] Compensation includes wages, salaries, and employers' cost of employee benefits when contract is negotiated.

[2] Adjustments are the net result of increases, decreases, and no changes in compensation or wages.

[3] Because of rounding total may not equal sum of parts.

p = preliminary.

26. Average specified compensation and wage adjustments, major collective bargaining settlements in private industry situations covering 1,000 workers or more during 4-quarter periods (in percent)

Measure	Average for four quarters ending--							
	1984			1985				1986
	II	III	IV	I	II	III	IV	I^p
Specified total compensation adjustments, settlements covering 5,000 workers or more, all industries:								
First year of contract	4.7	4.2	3.6	3.4	3.4	3.1	2.6	2.3
Annual rate over life of contract	3.5	3.2	2.8	2.6	2.7	2.7	2.7	2.6
Specified wage adjustments, settlements covering 1,000 workers or more:								
All industries								
First year of contract	3.5	3.2	2.4	2.4	2.4	2.4	2.3	2.0
Contracts with COLA clauses	4.6	4.5	2.9	2.5	2.3	1.9	1.6	1.6
Contracts without COLA clauses	2.7	2.3	2.1	2.4	2.4	2.7	2.7	2.2
Annual rate over life of contract	3.1	2.8	2.4	2.3	2.4	2.5	2.7	2.5
Contracts with COLA clauses	2.9	2.8	1.8	1.3	1.5	1.8	2.5	2.6
Contracts without COLA clauses	3.2	2.8	2.7	2.8	2.8	3.0	2.8	2.5
Manufacturing								
First year of contract	3.0	2.6	2.3	2.1	2.0	1.5	.8	.8
Contracts with COLA clauses	3.2	1.5	2.1	2.0	1.9	1.5	.8	.8
Contracts without COLA clauses	2.8	3.7	2.9	2.5	2.2	1.5	.9	.9
Annual rate over life of contract	3.1	2.8	1.5	1.4	1.5	1.6	1.9	1.8

[1] Data do not meet publication standards.

p = preliminary.

27. Average effective wage adjustments, private industry collective bargaining situations covering 1,000 workers or more during 4-quarter periods (in percent)

Effective wage adjustment	Average for four quarters ending–						
	1984		1985				1986
	III	IV	I	II	III^p	IV	I
For all workers:[1]							
Total	4.2	3.7	3.6	3.5	3.5	3.3	3.1
From settlements reached in period	1.0	.8	.7	.9	.9	.7	.6
Deferred from settlements reached in earlier period	2.1	2.0	2.2	1.9	1.8	1.8	1.7
From cost-of-living-adjustments clauses	1.2	.9	.7	.7	.8	.7	.8
For workers receiving changes:							
Total	5.0	4.4	4.5	4.2	4.3	4.1	4.0
From settlements reached in period	3.7	3.0	2.9	2.9	2.8	3.4	2.9
Deferred from settlements reached in earlier period	4.2	4.0	4.2	3.9	3.7	3.7	3.5
From cost-of-living-adjustments clauses	3.2	2.7	2.3	2.3	2.8	2.2	2.5

[1] Because of rounding total may not equal sum of parts.

28. Specified compensation and wage adjustments from contract settlements, and effective wage adjustments, State and local government collective bargaining situations covering 1,000 workers or more (in percent)

Measure	Annual average		Second 6 months 1985^p
	1984	1985	
Specified adjustments:			
Total compensation [1] adjustments, [2] settlements covering 5,000 workers or more:			
First year of contract	5.2	4.2	3.8
Annual rate over life of contract	5.4	5.1	5.3
Wage adjustments, settlements covering 1,000 workers or more:			
First year of contract	4.8	4.6	4.4
Annual rate over life of contract	5.1	5.4	5.6
Effective adjustments:			
Total effective wage adjustment [3]	5.0	5.7	4.1
From settlements reached in period	1.9	4.1	3.2
Deferred from settlements reached in earlier periods	3.1	1.6	.9
From cost-of-living-adjustment clauses	(4)	(4)	(4)

[1] Compensation includes wages, salaries, and employers' cost of employee benefits when contract is negotiated.

[2] Adjustments are the net result of increases, decreases, and no changes in compensation or wages.

[3] Because of rounding total may not equal sum of parts.

[4] Less than 0.05 percent.

^{p} = preliminary.

29. Work stoppages involving 1,000 workers or more

Measure	Annual totals		1985							1986					
	1984	1985	June	July	Aug.	Sept.	Oct.	Nov.	Dec.	Jan.^{p}	Feb.^{p}	Mar.^{p}	Apr.^{p}	May^p	June^p
Number of stoppages:															
Beginning in period	62	54	2	9	6	11	6	3	2	4	3	3	4	6	11
In effect during period	68	61	8	13	18	20	20	13	9	7	7	8	9	11	18
